Academic Journals

ABOUT JMGG

The **Journal of Medical Genetics and Genomics (JMGG)** is published monthly (one volume per year) by Academic Journals.

Journal of Medical Genetics and Genomics (JMGG) is an open access journal that provides rapid publication (monthly) of articles in all areas of the subject such as metagenics, evolutionary anthropology, fragile X syndrome, immunotherapy etc.
The Journal welcomes the submission of manuscripts that meet the general criteria of significance and scientific excellence. Papers will be published shortly after acceptance. All articles published in JMGG are peer-reviewed.

Submission of Manuscript

Submit manuscripts as e-mail attachment to the Editorial Office at: jmgg@acadjournals.org. A manuscript number will be mailed to the corresponding author shortly after submission.

The Journal of Medical Genetics and Genomics will only accept manuscripts submitted as e-mail attachments.

Please read the **Instructions for Authors** before submitting your manuscript. The manuscript files should be given the last name of the first author.

Editors

Editorial Board

Instructions for Author

Electronic submission of manuscripts is strongly encouraged, provided that the text, tables, and figures are included in a single Microsoft Word file (preferably in Arial font).

The **cover letter** should include the corresponding author's full address and telephone/fax numbers and should be in an e-mail message sent to the Editor, with the file, whose name should begin with the first author's surname, as an attachment.

Article Types

Three types of manuscripts may be submitted:

Regular articles: These should describe new and carefully confirmed findings, and experimental procedures should be given in sufficient detail for others to verify the work. The length of a full paper should be the minimum required to describe and interpret the work clearly.

Short Communications: A Short Communication is suitable for recording the results of complete small investigations or giving details of new models or hypotheses, innovative methods, techniques or apparatus. The style of main sections need not conform to that of full-length papers. Short communications are 2 to 4 printed pages (about 6 to 12 manuscript pages) in length.

Reviews: Submissions of reviews and perspectives covering topics of current interest are welcome and encouraged. Reviews should be concise and no longer than 4-6 printed pages (about 12 to 18 manuscript pages). Reviews are also peer-reviewed.

Review Process

All manuscripts are reviewed by an editor and members of the Editorial Board or qualified outside reviewers. Authors cannot nominate reviewers. Only reviewers randomly selected from our database with specialization in the subject area will be contacted to evaluate the manuscripts. The process will be blind review.

Decisions will be made as rapidly as possible, and the journal strives to return reviewers' comments to authors as fast as possible. The editorial board will re-review manuscripts that are accepted pending revision. It is the goal of the JMGG to publish manuscripts within weeks after submission.

Regular articles

All portions of the manuscript must be typed double-spaced and all pages numbered starting from the title page.

The Title should be a brief phrase describing the contents of the paper. The Title Page should include the authors' full names and affiliations, the name of the corresponding author along with phone, fax and E-mail information. Present addresses of authors should appear as a footnote.

The Abstract should be informative and completely self-explanatory, briefly present the topic, state the scope of the experiments, indicate significant data, and point out major findings and conclusions. The Abstract should be 100 to 200 words in length.. Complete sentences, active verbs, and the third person should be used, and the abstract should be written in the past tense. Standard nomenclature should be used and abbreviations should be avoided. No literature should be cited.

Following the abstract, about 3 to 10 key words that will provide indexing references should be listed.

A list of non-standard **Abbreviations** should be added. In general, non-standard abbreviations should be used only when the full term is very long and used often. Each abbreviation should be spelled out and introduced in parentheses the first time it is used in the text. Only recommended SI units should be used. Authors should use the solidus presentation (mg/ml). Standard abbreviations (such as ATP and DNA) need not be defined.

The Introduction should provide a clear statement of the problem, the relevant literature on the subject, and the proposed approach or solution. It should be understandable to colleagues from a broad range of scientific disciplines.

Materials and methods should be complete enough to allow experiments to be reproduced. However, only truly new procedures should be described in detail; previously published procedures should be cited, and important modifications of published procedures should be mentioned briefly. Capitalize trade names and include the manufacturer's name and address. Subheadings should be used. Methods in general use need not be described in detail.

Results should be presented with clarity and precision. The results should be written in the past tense when describing findings in the authors' experiments. Previously published findings should be written in the present tense. Results should be explained, but largely without referring to the literature. Discussion, speculation and detailed interpretation of data should not be included in the Results but should be put into the Discussion section.

The Discussion should interpret the findings in view of the results obtained in this and in past studies on this topic. State the conclusions in a few sentences at the end of the paper. The Results and Discussion sections can include subheadings, and when appropriate, both sections can be combined.

The Acknowledgments of people, grants, funds, etc should be brief.

Tables should be kept to a minimum and be designed to be as simple as possible. Tables are to be typed double-spaced throughout, including headings and footnotes. Each table should be on a separate page, numbered consecutively in Arabic numerals and supplied with a heading and a legend. Tables should be self-explanatory without reference to the text. The details of the methods used in the experiments should preferably be described in the legend instead of in the text. The same data should not be presented in both table and graph form or repeated in the text.

Figure legends should be typed in numerical order on a separate sheet. Graphics should be prepared using applications capable of generating high resolution GIF, TIFF, JPEG or Powerpoint before pasting in the Microsoft Word manuscript file. Tables should be prepared in Microsoft Word. Use Arabic numerals to designate figures and upper case letters for their parts (Figure 1). Begin each legend with a title and include sufficient description so that the figure is understandable without reading the text of the manuscript. Information given in legends should not be repeated in the text.

References: In the text, a reference identified by means of an author‘s name should be followed by the date of the reference in parentheses. When there are more than two authors, only the first author‘s name should be mentioned, followed by ’et al‘. In the event that an author cited has had two or more works published during the same year, the reference, both in the text and in the reference list, should be identified by a lower case letter like ’a‘ and ’b‘ after the date to distinguish the works.

Examples:

Abayomi (2000), Agindotan et al. (2003), (Kelebeni, 1983), (Usman and Smith, 1992), (Chege, 1998; 1987a,b; Tijani, 1993,1995), (Kumasi et al., 2001)
References should be listed at the end of the paper in alphabetical order. Articles in preparation or articles submitted for publication, unpublished observations, personal communications, etc. should not be included in the reference list but should only be mentioned in the article text (e.g., A. Kingori, University of Nairobi, Kenya, personal communication). Journal names are abbreviated according to Chemical Abstracts. Authors are fully responsible for the accuracy of the references.

Examples:

Chikere CB, Omoni VT and Chikere BO (2008). Distribution of potential nosocomial pathogens in a hospital environment. Afr. J. Biotechnol. 7: 3535-3539.

Moran GJ, Amii RN, Abrahamian FM, Talan DA (2005). Methicillinresistant Staphylococcus aureus in community-acquired skin infections. Emerg. Infect. Dis. 11: 928-930.

Pitout JDD, Church DL, Gregson DB, Chow BL, McCracken M, Mulvey M, Laupland KB (2007). Molecular epidemiology of CTXM-producing Escherichia coli in the Calgary Health Region: emergence of CTX-M-15-producing isolates. Antimicrob. Agents Chemother. 51: 1281-1286.

Pelczar JR, Harley JP, Klein DA (1993). Microbiology: Concepts and Applications. McGraw-Hill Inc., New York, pp. 591-603.

Short Communications

Short Communications are limited to a maximum of two figures and one table. They should present a complete study that is more limited in scope than is found in full-length papers. The items of manuscript preparation listed above apply to Short Communications with the following differences: (1) Abstracts are limited to 100 words; (2) instead of a separate Materials and Methods section, experimental procedures may be incorporated into Figure Legends and Table footnotes; (3) Results and Discussion should be combined into a single section.
Proofs and Reprints: Electronic proofs will be sent (e-mail attachment) to the corresponding author as a PDF file. Page proofs are considered to be the final version of the manuscript. With the exception of typographical or minor clerical errors, no changes will be made in the manuscript at the proof stage.

Fees and Charges: Authors are required to pay a $550 handling fee. Publication of an article in the Journal of Medical Genetics and Genomics is not contingent upon the author's ability to pay the charges. Neither is acceptance to pay the handling fee a guarantee that the paper will be accepted for publication. Authors may still request (in advance) that the editorial office waive some of the handling fee under special circumstances.

Submission of a manuscript implies: that the work described has not been published before (except in the form of an abstract or as part of a published lecture, or thesis) that it is not under consideration for publication elsewhere; that if and when the manuscript is accepted for publication, the authors agree to automatic transfer of the copyright to the publisher.

Full Length Research Paper

The codon 17 polymorphism of the *CTLA4* gene in type 1 diabetes mellitus in the Baghdad population

Najwa S. H. Ahmed

Biotechnology Research Center, Al-Nahrain University, Baghdad, Iraq.

Accepted 13 January, 2014

The aim of this work was to study the polymorphism in *CTLA4* gene in insulin-dependent diabetes mellitus (IDDM) type I patients in Baghdad population. To achieve this goal, blood samples were collected from 80 IDDM (40 males and 40 females) and 20 samples of healthy, DNA was isolated and the *CTLA4 gene* (A 152 bp fragment) were amplified by using specific primers for exon1 of this gene, and then found the sequence of this region. The DNA sequencing results of flank sense of *CTLA4* gene from healthy patients was found to be compatible (100%) with wild type of *Homo sapiens* from the Gene Bank, while 99% compatibility were found for the gene from 70 IDDM cases patients with wild type of gene. The difference may be attributed to one transition mutations, A/G at position 49 of the *CTLA4* gene (from AGC to AAC). It is a missense mutation that leads to changes in amino acid from serine (S) to asparagine (N). Our results showed that the incidence of A/G mutation at nucleotide position 49 and diabetes was highly significant (X^2 = 100, *P* < 0.01). In total, 12% of patients with IDDM (10 cases) had two transition mutation +49 A/G and +47 C/T single nucleotide polymorphism from total cases, 98% compatibility were found for that gene from 10 IDDM cases patients with wild type of gene. The +47 C/T SNP was silent mutation which resulted in change of codon from GGT to GGC but no changes translated to amino acid (glycine to glycine). However, there was no significant correlation between diabetes and incidence of C/T at nucleotide 47 (X^2 = 0.055, *P* > 0.05). In conclusion, our case study suggests that the +49 A/G SNP of the *CTLA4* gene is strongly associated with genetic susceptibility to type 1 diabetes mellitus in the Baghdad/Iraqi population.

Key words: *CTLA4* gene, insulin-dependent diabetes mellitus, A/G polymorphism.

INTRODUCTION

Cytotoxic T-lymphocyte antigen 4 (*CTLA4*) also known as cluster of differentiation 152 (CD152) is a protein that plays an important role in the immune system regulations. CTLA4 is a member of the immunoglobulin superfamily, which is expressed on the surface of Helper T cells and transmits an inhibitory signal to T cells. The *CTLA4* encodes the T cell receptor involved in the control of T cell proliferation and mediates T cell apoptosis (Yanagawa et al., 1997; Larsen et al., 1999). The receptor protein is a specific T lymphocyte surface antigen that is detected on cells only after antigen presentation. Thus, *CTLA4* is directly involved in both immune and autoimmune responses and may be involved in the pathogenesis of multiple T cell-mediated autoimmune disorders. The human *CTLA4* gene is located at chromosome 2q33 (Nistico et al., 1996; Donner et al., 1997a). This gene is a member of the immunoglobulin superfamily and encodes a protein which transmits an inhibitory signal to T cells. The protein contains a V domain of 116 amino acids, a

E-mail: Najwaun@yahoo.com

transmembrane domain, and a cytoplasmic tail. Alternate transcriptional splice variants, encoding different isoforms, have been characterized. The membrane-bound isoform functions as a homodimer which is inter-connected by a disulfide bond, while the soluble isoform functions as a monomer (Kristiansen et al., 2000).

An A-to-G substitution at nucleotide 49 in exon 1 results in an amino acid substitution (Thr/Ala) in the leader peptide of the protein (Donner et al., 1997b). The Ala allele has been shown to predispose the individual carrying it to the development of various immune diseases including insulin-dependent diabetes mellitus, Graves disease, Hashimoto thyroiditis, celiac disease, systemic lupus erythematosus, thyroid-associated orbitopathy, and other autoimmune diseases (Anjos and Polychronakos, 2004).

Mutations and polymorphisms in this gene results in alteration of the *CTLA4* activity and are believed to play an important role in the risk of developing autoimmunity (Anjos and Polychronakos, 2004). The *CTLA4* (49+) GG homozygous genotype is associated with Type 1 diabetes in Egyptian children especially with younger age of onset and in younger patients and not associated with grades of diabetic control or diabetic complication (Hatem et al., 2008; Mosaad et al., 2012). The aim of this study was to assess the contribution of this *CTLA4* polymorphism to the susceptibility to type 1 diabetes in the Baghdad population.

MATERIALS AND METHODS

Samples and DNA extraction

Whole blood samples were obtained from 80 Baghdad patients affected by insulin-dependent diabetes mellitus (IDDM) (40 males and 40 females, age ranged from 4 to 25 years). Samples from 20 healthy individuals were used as a control group. In total, 4 ml whole blood was collected into an Ethylenediaminetetraacetic acid (EDTA) tube. The samples were stored at -20°C until further processing. DNA was extracted by DNA extraction kit (Wizard® Genomic DNA Purification Kit, Promega, Madison, WI, USA) according to the manufacturer's protocol.

Amplification of exon 1 of *CTLA4* gene

A 152 bp fragment containing the +49 A/G polymorphism in exon 1 of *CTLA4* was amplified using a forward primer (*CTLA4*: 5′-AAGGCTCAGCTGAACCTGGT-3′) and a reverse primer (*CTLA4*: 5′-CTGCTGAAACAAATGAAACCC-3′) (Alpha DNA Company, Canada) (Marron et al., 1997). The polymerase chain reaction (PCR) amplification was performed in a total volume of 25 µl containing 5 µl DNA, 12.5 µl Go Taq green master mix 2X (Promega corporation, USA), 1 µl of each primer (50 pmol). The thermal cycling conditions were as follows: Denaturation at 94°C for 5 min, followed by 30 cycles of 94°C for 30 s, 57°C for 1 min and 72°C for 1 min with final incubation at 72°C for 7 min using a thermal Cycler (Gene Amp, PCR system 9700; Applied Biosystem) (Genc et al., 2004; Hatem et al., 2008). The PCR products were separated by1.5% agarose gel electrophoresis, stained with ethidium bromide and visualized by ultraviolet light (302 nm).

Sequencing and sequence alignment

Sequencing of exon 1of *CTLA4* gene was performed by Macro gen company, USA. Homology search was conducted using Basic local alignment search tool (BLAST) program which is available at the National Center Biotechnology Information (NCBI) online at (http://www.ncbi.nlm.nih.gov) and BioEdit program. The results were compared with data obtained from Gene Bank published ExPASY program which is available at the NCBI online.

Statistical analysis

The statistical analysis is a very important final step in the research to analyses and evaluates the obtained results. Medical statistics of this study was conducted via computer based statistical program which was: X^2 for Windows computer package. The statistical analysis tests used in this were as follows: P value < 0.01 is considered a significant correlation.

RESULTS AND DISCUSSION

CTLA4 gene was successfully amplified using specific PCR primers for exon 1. Figure 1 showed PCR amplification of exon 1 of the *CTLA4* where a specific product at 152 bp was observed. Our result is in agreement with other studies (Hatem et al., 2008; Waterhouse et al., 1995). Sequencing of this gene was performed to detect variant +49A/G which related to development of diabetes. Sequences alignment using BLAST and BioEdit showed the 100% similarity or homology of healthy sample with wild type of the *CTLA4* gene of *H. sapiens* from the Gene Bank (Figure 2). The *CTLA4* gene from 70 diabetes patients shows 99% compatibility with the wild type sequences of *CTLA4* gene from Gene Bank as shown in Figure 3A, there are one transition at position +49 A/G single nucleotide polymorphism that cause a serine to aspargine substitution in codon 17, there is a high significance between diabetes and incidence of + 49 A/G position in exon 1 of *CTLA4* gene (X^2 = 100, P > 0.01), Table 1 shows the type of mutation and the effect of these mutations and Table 2 shows the translation of *CTLA4* gene of all groups (healthy and patient) to a protein sequence, and two transition mutation at position +47 C/T and +49 A/G of *CTLA4* gene from 10 diabetes patients was identified.

The sequence shows 98% compatibility with wild type *CTLA4* gene as shown in Figure 3B. single nucleotide polymorphism at position 47+ C/T that silent mutation, no change translate amino acid (Glycine to Glycine), there is lower significant correlation between type 1 diabetes and incidence of this SNP, (X^2 = 0.055, P > 0.05). Most molecular epidemiology studies have evaluated the role of the +49A/G single nucleotide polymorphism that causes a threoine to alanine substitution in codon 17 and associated with altered protein expression (Anjos et al., 2002) and T-cell activation (Maurer et al., 2002). Gribben et al. (1995) have suggested that this may be through antigen specific induction of the apoptotic pathway. The mentioned study investigated the A49G polymorphism in

Figure 2. Sequencing of sense flanking the partial *CTLA4* gene for healthy as compared with wild type *CTLA4* obtained from Gene Bank.

exon 1 of *CTLA4* gene in 40 Lebanese and 46 controls from the same ethnic background.

An increase in the frequency of the G allele was discovered in patients when compared to control subjects, this difference was statistically significant, despite the small sample size. Wafai et al. (2011) showed an association of *CTLA4* with type 1 diabetes in Lebanese population. An association was detected between the *CTLA4* gene polymorphism and younger-onset type 1 diabetes with autoimmune thyroid disease (AITD) (Gough, et al., 2005).. The G variant was suggested to be genetically linked to AITD-associated type 1 diabetes of younger onset in this Japanese population (Mochizuk, et al., 2003). The defect in these patients presumably lies in a T-cell mediated autoimmune mechanism (Takara et al., 2000). Chistiakov et al. (2001) reported that the *CTLA4* gene is strongly associated with insulin-dependent diabetes mellitus (IDDM) in a fifty-six families each consisting of two siblings (one affected with IDDM diagnosed before the age of 18 years and one non-diabetic sibling).

It was reported that the *CTLA4* 49 (A/G) mutation conferred a risk of type 1 diabetes in the Chinese children but not in the West African children. On the other hand, the novel *CTLA4* 159 (C/G) mutation conferred a risk of type 1 diabetes in the West African children but not in the Chinese type 1 diabetic children (Hyiaman et al., 2001). Donner et al. (1997b) showed that an alanine at codon 17 of *CTLA4* is associated with genetic susceptibility to Graves disease as well as to IDDM. Lemos et al. (2009) states that the *CTLA4* +49 A/G polymorphism is not associated with susceptibility to type 1 diabetes mellitus in the Portuguese population. This contrasts with positive associations that have been reported for the +49A/G polymorphism in case control studies in populations from Belgium, Germany, Poland, France, Japan, China, Italy, the Philippines, Lebanon, Estonia and Iran (Zalloua et al., 2004; Kavvoura and Ioannidis, 2005; Mojtahedi et al., 2005). However, lack of association for the + 49A/G polymorphism has also been reported in populations from the USA, Japan, Ghana, UK, France, Czech Republic, Morocco, Argentina, Brazil and Azerbaijan (Marron et al., 1997; Caputo et al., 2005; Hauache et al., 2005; Kavvoura

and Ioannidis, 2005; Ahmedov et al., 2006).

Conclusion

Our study showed that there was significant correlation between diabetes and incidence of A/G +49 position in exon 1 of *CTLA4* gene, despite the limited size of our sample, our results together with population studies show an association of *CTLA4* with type 1 diabetes mellitus, on the other hand, the novel of +47 C/T silent mutation was no significant correlation between type 1 diabetes in

Baghdad population.

Noonan syndrome is a genetic autosomal dominant disorder characterized by facial dysmorphy, short stature, delayed puberty and congenital heart defects. The first gene implicated in this syndrome is PTPN11, encoding protein tyrosine phosphatase SHP-2. Several studies worldwide have identified missense mutations in this gene in patients with Noonan syndrome. Our objective focused on mutations screening of PTPN11 on a Senegalese population with Noonan syndrome. Six patients clinically diagnosed with Noonan syndrome were included in this study. DNA was extracted from whole blood by phenol chloroform. Mutation screening was performed by bidirectional sequencing of amplified polymerase chain reaction (PCR) products of PTPN11 exons frequently mutated in Noonan syndrome. This study identified in two patients, a c.923A>C mutation in exon 8, predicting Asn308Thr (N308T) on SHP-2 protein. This is the first time that this mutation is described in Noonan syndrome in Africa, while codon 308 was reported as a hot spot mutation site in other populations. Frequently reported amino acid substitutions were Asn308Asp and Asn308Ser. All these mutations affected the protein tyrosine phosphatase domain (PTP) of SHP-2 protein exerting a gain of function which would likely explain observed phenotypes in patients.

Key words: Mutation, N308T, protein tyrosine phosphatise (PTP), SHP-2 protein, Noonan syndrome, Senegal.

INTRODUCTION

Noonan syndrome (NS, MIM 163950) is an autosomal dominant dismorphic syndrome described first by Noonan (1968). The prevalence of NS is estimated to be 1 in 1000 to 2500 births. The disease is characterized by proportionate short stature, delayed puberty, congenital heart defects and multiple minor anomalies such as hypertelorism, malrotated ears, webbed neck, bleeding diathesis, cryptorchidism in males, mental retardation, and hearing difficulties (Marino et al., 1999; Roberts et al., 2013; van der Burgt et al., 2007). The most common congenital heart defect is pulmonary valve stenosis with displastic leaflets followed by hypertrophic obstructive cardiomyopathy (HC), atrial septal defects (Marino et al., 1999; Musante et al., 2003; Tartaglia et al., 2006).

Jamieson et al. (1994) mapped a gene for NS to the long arm of chromosome 12 (12q24). Tartaglia et al. (2001) reported that NS is caused by heterozygous missense mutations of the gene protein-tyrosinephosph-

*Corresponding author. E-mail: dabafr@yahoo.fr. Tel: 00 221 77 520 21 46.

atase nonreceptor type 11 (PTPN11) located on 12q24. PTPN11 mutations were detected in 45% of unrelated individuals with sporadic or familial NS (Tartaglia et al., 2002).PTPN11 gene consists of 15 exons and the expressed protein encodes cytoplasmic tyrosine phosphatase with two tandemly arranged Src homology 2 (SH2) domains (N-SH2 and C-SH2) at the N terminal region and a C terminal protein-tyrosine phosphatase domain (PTP) (Chan and Feng, 2007). The PTPN11 gene is widely expressed in various human tissues, especially in the heart, brain, and skeletal muscle (Ahmad et al., 1993). The protein plays a critical role in regulating the response of eukaryotic cells to extracellular signals through the RAS/MAPK pathway (Roberts et al., 2013).

All PTPN11 missense mutations associated with NS were clustered in the interacting portions of the N-SH2 domain and the PTP domains are involved in switching the protein from its inactive to the active conformation. Functional studies by energetic-based structural analysis of two N-SH2 mutants revealed that those mutations favoured the active conformation of PTPN11 protein, resulting in a gain-of-function effect (Tartaglia et al., 2001; Uhlen et al., 2006). Also, other studies have reported enhanced phosphatase activity of NS mutants located in the SH2 and PTP domains (Niihori et al., 2005; Tartaglia et al., 2003).

Understanding of the molecular genetic causes of NS, enable the study of the pathophysiological mechanisms underlying the varied medical and developmental features of NS. PTPN11 belongs to the RAS-MAPK pathway which is an important signal transduction pathway. Mutations that cause NS deregulated this pathway leading to the clinical features observed. Furthermore, all the other genes implicated in NS including SOS1, RAF1, and KRAS encode proteins integral to this pathway (Roberts et al., 2013).

Several studies have reported mutation analysis of PTPN11 gene and genotype-phenotype correlation in NS in different geographical regions (Bertola et al., 2004; Pierpont et al., 2009; Sznajer et al., 2007; Tartaglia et al., 2006; Yoshida et al., 2004). Mutation screening in NS patients from United States showed that all mutations are exonic changes with the majority clustering in exon 3 and 8. The most common mutation was a c.922A>G in exon 8, leading to the Asn308Asp substitution within the PTP domain (Tartaglia et al., 2002). The occurrence of an adjacent c.923A>G mutation predicting an Asn308Ser change and c.923A>C (Asn308Thr) indicated that codon 308 is a hot spot site for NS with a frequency of 36% in PTPN11 mutated patients (Tartaglia et al., 2002; Tartaglia et al., 2006; Tartaglia et al., 2003). Other studies have reported the occurrence of different mutations types of PTPN11 in European and Asian populations. In Germany, the most common mutation is c.188A>G (Tyr63Cys) followed by c.922A>G (Musante et al., 2003), while in Japan the most common mutation is c.236A>G (Gln79Arg) (Yoshida et al., 2004). In Africa, few studies have focused on mutation screening in NS. Only one report from Morroco identified the c.922A>G mutation in two affected siblings with normal parents (Elalaoui et al., 2010) and c.182A>G (Ratbi et al., 2008). In sub-Saharan Africa, no report from PTPN11 mutation is available to date. The objective in this study was to screen for PTPN11 gene mutations in 6 Senegalese patients with NS and summarized observed clinical features.

POPULATION AND METHODS

Patients and clinical assessment

After informed consent, 6 patients clinically diagnosed with NS were included in this study. Patients were examined by clinicians from the Cardiology Unit of Fann Hospital in Dakar (Senegal), who have experience with NS. Electrocardiograms, echocardiograms and clinical photographs were obtained from each patient. NS was diagnosed on the basis of the presence of the following major characteristics: typical facial dysmorphy, pulmonary valve stenosis or hypertrophic cardiomyopathy, chest deformity, developmental delay and cryptorchidism in male patients. To be diagnosed for NS, patient with facial dysmorphy had to have at least two of the major characteristics (van der Burgt et al., 1994).

Mutation screening of PTPN11 gene

Genomic DNA was isolated from peripheral blood lymphocytes by classic phenol/chloroform method. The most frequently mutated exons reported in NS (3, 4, 7 and 8) and flanking introns of PTPN11 gene were amplified by PCR with sets of primers as described previously (Tartaglia et al., 2002). All PCR products were purified with QIAquick PCR purification kit from Qiagen™ as described by the manufacturer. Mutations were screened by direct bidirectional sequencing of the purified PCR products with Big Dye Terminator chemistry (Perkin Elmer Biosystem™) on an ABI 3100 auto sequencer (ABI™, Foster City, CA). Obtained sequences were analysed by BioEdit software (Hall, 1997).

RESULTS AND DISCUSSION

Clinical features of studied NS patients are summarized in Table 1. In this study, 4 females and 2 males were recruited with ages ranging from 1 to 31 years. None of the patients had known family history of NS. Growth was delayed in all cases. Dysmorphic features were present with variable severity in all cases. Figure 1 illustrates some of these features (hypertelorism, low-set ears, webbed neck, chest deformity, and ptosis) in a male and a female patient. The most frequent cardiac abnormalities were hypertrophic cardiomyopathy (HCM) and pulmonary valve stenosis (PS). One of the male cases had cryptorchidism.

The phenotypes observed in NS are heterogeneous and vary in different ages. The diagnosis of Noonan syndrome is primarily clinical and is guided by the most common dysmorphic signs such as hypertelorism, low-

set ears, chest deformities and short stature, associated cardiac abnormalities (Tartaglia et al., 2002; van der Burgt, 2007; van der Burgt et al., 1994). These morphological abnormalities were observed in most of our patients and were the key elements of diagnosis.

In addition to these morphological abnormalities, alterations in several genes have been implicated in NS. This is the case of the PTPN11 gene which is mutated in 40 to 50% of patients with NS (Tartaglia et al., 2001). Mutation screening of PTPN11 gene in studied exons have identified a heterozygote substitution in exon 8, c.923A>C, in two unrelated patients NS5 and NS6 (Figure 2). This missense mutation led to N308T substitution on the PTP domain of SHP-2 protein. This mutation has not been detected in 15 healthy Senegalese controls.

The mutation rate found in our study (2 of the 6 studied patients) is lower than reported in other populations (Hung et al., 2007; Tartaglia et al., 2002). This difference could be explained, first by the small number of patients enrolled, due to the absence of a clinical consultation in dysmorphology at health facilities in Senegal. The six patients recruited are indeed followed up in the Cardiology Unit of Aristide Le Dantec Hospital for their associated heart abnormalities. Secondly, this study only have sequenced the exons 3, 4, 7 and 8 which are most frequently mutated in NS but mutations may be observed in other exons not studied (Musante et al., 2003; Yoshida et al., 2004). Thirdly, PTPN11 is not the only gene associated with NS. Mutations have also been reported in genes such as KRAS, RAF, SOS1 all involved in the same signaling RAS/MAP pathway (Roberts et al., 2013).

The c.923A>C mutation observed in our study is heterozygous and confirms the autosomal dominant transmission of NS. This mutation leads to the substitution of N308T in SHP-2 protein. It is the first time that this mutation is reported in African patients with NS. Two previous studies have reported this mutation in USA in 3 individuals without any details about their Caucasian or African-American ethnic origin (Pierpont et al., 2009; Tartaglia et al., 2006) (Table 2). It was hypothesized that N308T as de novo mutation may

Figure 1. Two NS patients: (A and B) a 4 year old boy (NS3) without mutations in studied exons of PTPN11 gene, typical signs of dysmorphy are ptosis, hypertelorism, webbed neck, chest deformity; (C and D) a 4 year old girl (NS6) with mutation c.923A>C in exon 8 of PTPN11 gene, typical signs of dysmorphy are low set ears, hypertelorism, webbed neck.

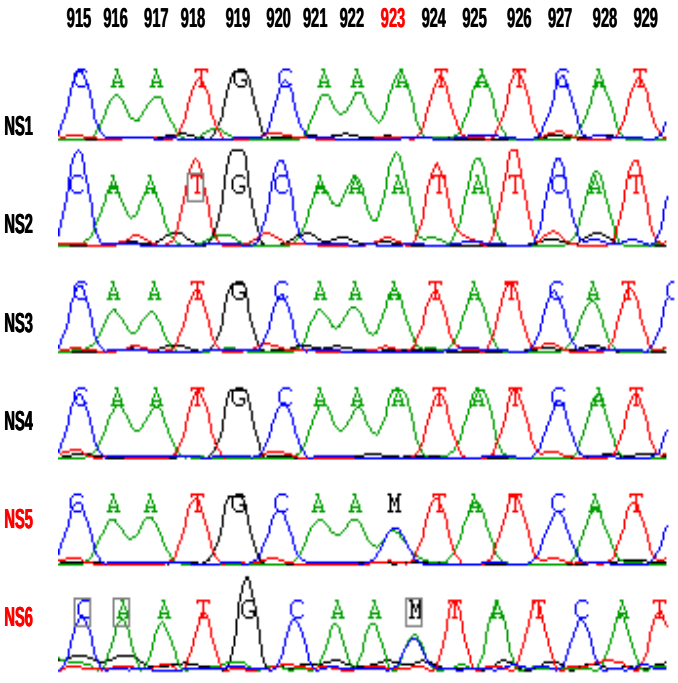

Figure 2. Sequence plots alignment around position 923 of exon 8 of PTPN11 gene in studied patients. NS1 to NS4 are homozygous for the wild type allele at position 923 (genotype A/A); NS5 and NS6 have a heterozygous mutation c.923A>C (genotype A/C).

arise first in Africa. It may be confirmed by investigating the ethnic origin of US patients bearing this mutation.

Although, position 308 of SHP-2 protein have been reported to be the most frequently mutated site in NS, amino-acid substitution reported were mostly N308D and N308S (Keren, 2006; Musante et al., 2003; Tartaglia et al., 2001). These mutations are located in the PTP domain of SHP-2. Crystallographic data have shown that the PTP domain as the SH2 domain play an important role in the stability and function of the SHP-2 protein (Musante et al., 2003; Tartaglia et al., 2001). Amino-acid changes in interaction sites between PTP and N-SH2 domains or near these sites may lead to the switch of SHP-2 protein from its inactive form to an active form, which result in a dominant positive effect on the activation of the RAS/MAPK signaling pathway effect. This activation is responsible for the morphological and cardiac anomalies in Noonan syndrome as reported in mouse model (Chen et al., 2010; Lapinski et al., 2013). Although inactivation of this pathway can rescue congenital heart defects and craniofacial malformations in Noonan mouse model (Nakamura et al., 2007, 2009).

It is also established that N308D mutation lead to a milder hyperactivation of the RAS/MAPK pathway compared to other described mutations in the PTPN11 gene (Oishi et al., 2006). Similarly, patients with Noonan syndrome and carrying this mutation have normal psychomotor development (Sznajer, 2009). This is not the case with the mutated patients in our study (NS5, NS6), which showed growth delay. This could be explained by the difference of involved amino acids. Indeed, it would be appropriate to consider functional studies on mutation N308T in order to evaluate its effect on the SHP-2 protein activity.

Conclusions

This study focused on finding the PTPN11 gene mutations involved in Senegalese patients with Noonan syndrome. Two patients in six had a heterozygous mutation, c.923A>C in exon 8 of PTPN11 gene, resulting in amino acid change Asn308Thr in SHP-2 protein. This is the first time that this mutation is described in Noonan syndrome in Africa although position 308 is considered as a "hot spot" site. The results presented are preliminary results of a pilot study of the PTPN11 gene in Senegalese patients with Noonan syndrome and currently followed in the health services in Dakar.

ACKNOWLEDGEMENTS

The authors thank the patients and their families for their interest in this study. They also thank clinicians of the Cardiology Unit of Aristide le Dantec Hospital and Fann Hospital for patient recruitment.Thanks to the Parasitology Laboratory of University Cheikh Anta Diop and the

Molecular Biology Laboratory of Aristide Le Dantec Hospital for providing technical facilities. Funding for this work came from the Third World Academy of Science (RGA/ N° 07-053RG/BIO/AF/AC).

Accepted 25 March 2013

In this study, we investigated the correlation between CYP2C9 gene polymorphism and maintenance dose of Warfarin in 300 patients who were the Han population derived from the Affiliated Yan An Hospital of Kunming Medical University in Yunnan Province of China, subjected to the operation of cardiac valve replacement and Warfarin oral administration post operation from 2008 to 2009 by detecting the genotypes and Allele Frequency at the three candidate loci (CYP2C9*2, CYP2C9*3 and CYP2C9*c_65) of CYP2C9 gene from the blood samples. Polymerase chain reaction -restriction fragment length polymorphism (PCR-RFLP) assay and DNA sequencing were used to ascertain the genotypes and their corresponding distribution rate. The maintenance dose of Warfarin administered in anticoagulant therapy among the CYP2C9*3 genetypes found in our experiment showed: A/A wild type > A/C heterozygote>C/C homozygote, suggesting that patients with C mutation need the lowest maintenance dose of Warfarin among the three genotypes found in this study. Our results will shed a new light on the personalized medicine of Warfarin and provide basic and genetic experimental data and foundation for future studies with regard to multiple genes' effect on Warfarin dorsage in anticogulantant therapy.

Key words: Warfarin, maitenance dosage, CYP2C9, gene polymorphism, single nucleotide polymorphism (SNP), restriction fragment length polymorphism (RFLP), correlation.

INTRODUCTION

As a kind of common oral anticoagulant, Warfarin is extensively applied for the anticoagulant therapy in various diseases, including valvular heart disease or pathological conditions, valve replacement, fibrillation atrial, electrical conversion, coronary heart disease, pulmonary embolism, deep vein thrombosis and stoke e.t.c. Along with the elevation of incidence rate in chronic fibrillation atrial, cardiovascular and cerebrovascular diseases related to thrombo embolism occur more than ever before. Additionally, the popularity of artificial cardiac valve replacement results in more and more patients receiving long-term oral administration of Warfarin for anticoagulant

#ZhiYu Chen and Jintao Li contributed equally to this work.

therapy. However, in the clinical practice of anticoagulant therapy, it is difficult to control the effective maintenance dose of Warfarin, due to the large variation with regard to intra-individual difference in maintenance dose of anticoagulant agent, its therapeutic effect and side effect (Aithal et al., 1999).

Inadaptable dose of Warfarin administration, especially over dose may lead to some serious complications including hemorrhage or thrombosis, even a threat to life. In the early stage of Warfarin administration, the incidence rate of hemorrhage is about 12%, and death rate resulted from hemorrhage in patients is 2% (Levine et al., 2001). It is reported that in America, there are about 2 million patients who were suffered from the side effect of drugs, half of which were lethal (Lazarou et al., 1998). Therefore, to make a change for traditional medication mode into personalized medicine will shed a new light on the settlement of this difficulty by adjusting the Warfarin dose as optimal one suitable for patients and, at the same time, reducing the side effect of it.

To date, among the studies of gene polymorphism of CYP2C9, the most studied and extensive ones were involving in the correlation between mutation of either CYP2C9*2 or CYP2C9*3 and clinical Warfarin maintenance dosage (Higashi et al., 2002). Furthermore, there exists large variation in Allele Frequency of CYP2C9*2 and CYP2C9*3 among different races. However, until now, there are few reports about the roles of gene loci of CYP2C9 in Warfarin administration, and the guidance of Warfarin personalized medication needs intensive study.

In this study, we investigated the correlation between the gene polymorphism of three important gene loci (CYP2C9*2, CYP2C9*3 and CYP2C9*c_65) in CYP2C9 gene and Warfaring maintenance dosage administered in anticogulatant thrapy, so as to pave a new way for the personalized medicine of Warfarin according to different genotypes of different patients.

MATERIALS AND METHODS

Object of study

Sample harvesting and Admission standard of patients

A total of 300 patients of Han population who were subjected to cardiac valve replacement from 2008 to 2009 in Affiliated Yan An Hospital of Kunming Medical University in Yunnan Province of China were registered and recruited according to the strict standard (see below) in this study. After informed consent was signed, a total of 3ml peripheral veinous blood was extracted from each patient. The blood samples were anticoagulated by addition of ethylenediaminetetraacetic acid (EDTA) and preserved at -48°C.

All 300 patients, more than 18 year-old, were orally administered with Warfarin for anticoagulant therapy under strict monitor persisted for one month post of operation, whose intertional normalized ratio (INR) range from 1.5 to 3.0. In the retrospective whole therapies of the patients were performed at this Hospital.The Warfarin tablets administered to all these patients were produced from the same pharmaceuticals company (Orion Corporation). The strict monitor index consisted of normal hepatic function and obeying dietetic contraindication according to the medical order. Clinical therapeutic and laboratory data were recorded in detail.

Exclusion standard of samples

Under following circumstances, the patients were excluded outside of this study:The patients who had liver diseases at present and before, or his (her) serum transaminase was 1.5 fold more than that of normal level. Patients with impaired renal function, whose serum creatinine >120 μmol/L. In the prospective cases, Warfarin was orally administered three months prior to this test. Patients who were administered or administering the drugs influenced the metabolism of Warfarin Herman et al. (2006) Basal INR scale>1.4 - patients who were not appropriate for Warfarin administration due to other reasons.

Definition of target International normalized ratio (INR) scale and stable dorsage of Warfarin

International normalized ratio (INR)

Since Professor Armand Quick (1935_a, 1935_b) set up routine prothrombin time (PT) blood cogulation assay in 1935, untill now, it is still an important screen test to measure factors and associated inhibitors in exogenous blood coagulation system. However, the outcome of PT assay was influenced by various factors. Therefore, it must undergo standardization and quality control so as to elevate its precision, accuracy and reliability. In recenty years, international normalized ratio (INR) detection was adopted extensively to measure the clotting time, which avoids the differential outcomes in different detections due to different reagents used in this assay.

Target International normalized ratio (INR) in this study

In this study, the scales of INR measured from blood samples of patients were screened by the standard ranging from 1.5 to 3.0, downward for 0.2 was considered as the normal. The patients whose INR were outside of this range were excluded from this study, because under this situation, the Warfarin dose could not attain stablility, which is unfavorable to our study and may produce a misleading and even false outcome.

Stable dosages of Warfarin

Stable dosage of Warfarin was referred to: under the same dosage of Warfarin, sequential INR detection of patients ranged from 1.5 to 3.0. The interval of two INR tests was at least above 7 days.

Primer synthesis

The primers used in the PCR assay were synthesized by Sai Bai Sheng Gene Technology Co. Ltd. Primers of these 3 candidate gene loci were as follows:

CYP2C9*2: locates at 3rd exon
Single Nucleotide Polymorphism (SNP) name: rs1799853
Upriver primer 5'-ATGGAAAACAGAGACTTACAGAGGT -3'
Downstream primer 5'- CCAGTAAGGTCAGTGATATGGAGTAG -3'
CYP2C9*3: locates at 7th exon SNP name: rs1057910
Upriver primer 5'- CTGAATTGCTACAACAAATGTGCCA -3'
Downstream primer 5'- AGGCTGGTGGGGAGAAGGTCC -3'
CYP2C9*c_65: locates at 3rd exon SNP name：rs9332127 Upriver primer 5'- TTTTTGCTGTTAAGGGAATTTG -3'
Downstream primer 5'- CAATTCAGAGCTTGATCCATG -3'

Table S1. Contents and quantities of PCR reaction system.

Contents of PCR reaction systen	Gene locus		
	CYP2C9*2 (guantity: μl)	CYP2C9*3 (guantity: μl))	CYP2C9*c_65 (guantity: μl))
Distilled water (PH8.2)	14	13	14
10×PCR Buffer	2.0	2.0	2.0
DNA template (250ng/μl)	1.0	2.0	1.0
dNTP	2.0	2.0	2.0
Upriver primer	0.5	0.5	0.5
Downstream primer	0.5	0.5	0.5
TaqDNA polymerase (5U/μl)	0.2	0.15	0.2

Table S2. Contents and quantities of the digestion system of CYP2C9*2, CYP2C9*3 and CYP2C9*c_65 gene locus.

Contents in Digestion system	Gene locus		
	CYP2C9*2 (Quantity: μl)	CYP2C9*3 (Quantity: μl)	CYP2C9*c_65 (Quantity: μl)
Distilled water (PH8.2)	7.7	5.7	6.7
10 × Buffer (AvaⅡ)	0.8	0.8	0.8
Restrictive endonuclease (10u/ μl)	0.5	0.5	0.5
Products of PCR amplification	1.0	3.0	8.5

Selection of restrict endonuclease

CYP2C9*2: restrict enzyme of AvaⅡ recognition site: GGTC*C
CYP2C9*3: restrict enzyme of Mva1 recognition site: CCA*GG
CYP2C9*c_65: restrict enzyme of HpaⅠ recognition site: GTT*AAC

DNA extraction

Saturated phenol/ chloroform method was employed according to traditional procedure described previously by Joanna et al. (2012) to extract DNA from the blood samples of 300 patients who were recruited for this study.

DNA purification and concentration assaying were performed as described in Alessandra et al. (2011) report.

Primer dilution

The pairs of primers used in PCR amplification were diluted and adjusted at the concentration of 20 pmol/μl referred to following fomula:

$$\text{Volume of distilled water added (μl)} = \frac{2 \times \text{number of nmolof synthtized primer} \times 10^3}{40}$$

Following dilution, the primer solution was subpackaged and stored at -48°C, awaits further usage.

PCR amplification

PCR reaction systems are shown in Table S1. Pure water, 10×PCR reaction buffer, DNA template, dNTP, primers and Taq DNA polymerase was added into 0.2 ml sterile microcentrifuge tube respectively and orderly, covered by paraffin oil. The tubes were placed into the PCR amplifier (GeneAmp PCR SYSTEM 9700, AB applied Biosystems) under conditions set up as following:

PCR reaction conditions of CYP2C9*2, CYP2C9*3 and CYP2C9*c_65 were shown below respectively:

97°C 5 min → 80°C 5 min → 94°C1min →60°C 1 min → 72°C 1 min → 72°C 10 min
30 cycles
97°C 5 min → 80°C 5 min → 94°C 30 s → 64.5°C 30 s → 72°C 30 s →72°C 10 min
30 cycles
97°C 5 min →80°C 5 min → 94°C 30 s → 55°C 30 s → 72°C 30 s → 72°C 10 min
30 cycles

After PCR reaction was finished, the products obtained from PCR were taken out and stored at -20°C.

Digestion by nucleate endonuclease

Restrictive endonuclease AvaⅡ, Mva1 and HpaⅠ were used for digestion in target fragment of CYP2C9*2, CYP2C9*3 and CYP2C9*c_65 gene loci respectively. The contents and quantities of the digestion system of CYP2C9*2, CYP2C9*3 and CYP2C9*c_65 gene loci were shown in Table S2. The digestion reaction was perfomed in a thermostatic waterbath at 37°C for 14 h.

Electrophoresis test for products from PCR amplication and digestion

In this test, 8% vertical native polyacrylamide gel electrophoresis

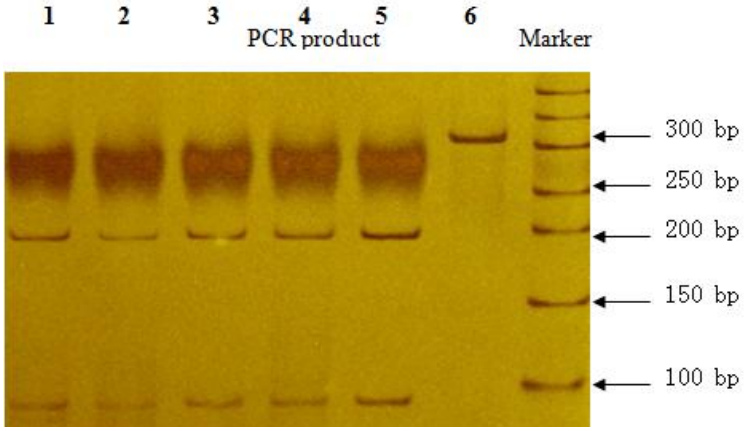

Figure 1. Samples 1 to 5 showed the digestive products following PCR, their genotypes were all C/C wild type Sample 6 showed PCR product of CYP2C9*2 locus, whose segment size was 309 bp. Number 1 was heterozygotemutant A/C (127, 105, 75 and 22 bp), Number 2 was homozygote mutant C/C (105, 75 and 22 bp), Number 3 to 5 was wild type A/A (127 and 75 bp), Number 6 was the product of PCR amplification of CYP2C9*2 locus, with segment size of 202 bp.

was employed. Silver Nitrate staining was used to observe the outcomes of the electrophoresis. By using 50 and 100 bp DNA ladder as standard molecular weight markers, the lengths of DNA fragments of target genes were ascertained and their genotypes were determined. Silver Nitrate staining method was used for coloration. Camera (Canon, IXY DIGITAL) was used to take pictures of the staining outcome. Dry gelatin was made so as to preserve the outcome.

DNA sequencing

DNA sequencing of three loci of CYP2C9 gene following PCR amplification

The products of PCR amplification of CYP2C9*2 (rs1799853), CYP2C9*3 (rs1057910) and CYP2C9*c_65 (rs9332127) were subjected to DNA sequencing. A total of 5 DNA samples from each locus were used for DNA sequencing in order to ascertain whether the PCR amplification products was the expectant target fragments. 3130-Genetic Analysis Apparatus (ABI Company, America) was employed to perform automatic DNA sequencing.

DNA sequencing of three loci of CYP2C9 gene following PCR amplification and digestion

The digestive products underwent DNA sequencing at CYP2C9*3 (rs1057910) locus consisted of 5 cases of A/A wild type (127 bp, 75 bp), 1 case of C/C homozygote mutation type (105 bp, 75 bp , 22 bp) and 2 cases of A/C heterozygote mutant (127 bp , 105 bp , 75 bp ,22 bp).

The DNA sequencing for the digestive products of CYP2C9*c_65 (rs9332127) locus following PCR amplification included 5 cases of G/G wild type (317 and 54 bp) and 2 cases of G/C heterozygote mutant (371, 317 and 54 bp).

Statistical analysis

Experimental data were expressed as mean±SD and analyzed by SPSS15.0 and PLINK software. Hardy-Weinberg law of genetic equilibrium was employed to detect the goodness of fit-test of genetic balance. The genotypes and allelotype frequency of three gene loci of CYP2C9 were calculated. χ^2- *t*est was used to analyze the data of genotypes and allelotype-frequency. A level of $p<0.05$ was considered as statistical significance.

RESULTS

Products of PCR amplification and genotypes of three loci of CYP2C9 gene

The segment size of CYP2C9*2 locus derived from the PCR and digestion in 300 DNA samples was all 309 bp (Figure 1) With the digestion by restrictive endonuclease AvaⅡ, when restriction enzyme cutting site was at base C, fragment of 309 bp-product following PCR was digested into three frangments, whose segment size was 195, 91 and 23 bp respectively. When restriction enzyme cutting site was at base T, the fragment of product following PCR could be digested into two fragments, whose segment size was 286 and 23 bp respectively. Only one allele- C (195, 91 and 23 bp) and one kind of genotype- C/C wild type (Figure 1) was checked out in the 300 samples. Among the 300 DNA samples, there was no mutational site was detected at CYP2C9*2 gene locus. As the digestive product of 23 bp fragment at CYP2C9*2 locus was the smallest one, when polyacrylamide gel electrophoresis (PAGE) finished, this fragment have run out of the gelatin, image of this fragment could not be observed within the gelatin. Only the 195 and 91 bp DNA fragments could be observed.

The segment size of CYP2C9*3 locus obtained from the PCR and digestion in 300 DNA samples was all 202

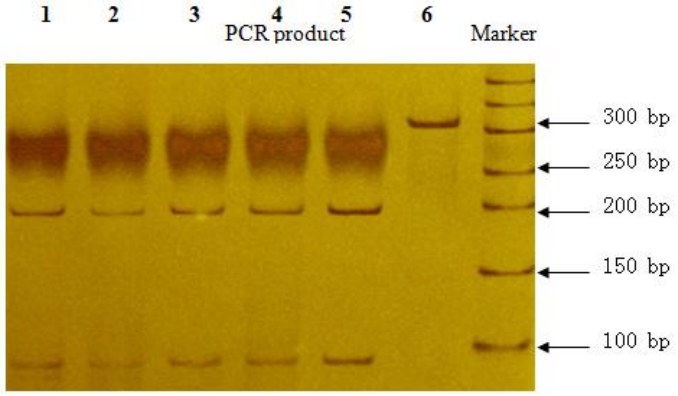

Figure S1. Samples 1 to 5 showed the digestive products following PCR, their genotypes were all C/C wild type. Sample 6 showed PCR product of CYP2C9*2 locus, whose segment size was 309 bp.

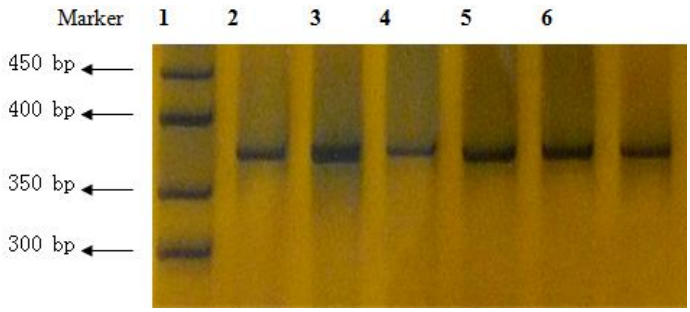

Figure S2. Number 1 to 6 showed PCR amplified fragments of CYP2C9*c_65 locus, with segment size of 371 bp.

bp (Figure S1). With restrictive nuclease va1 digestion, when the restriction enzyme cutting site was at base A, the 202 bp DNA fragments were digested into two fragments, whose segment size was 127 and 75 bp respectively. When the restriction enzyme cutting site was at base C, the DNA fragments (202 bp) were digested into three fragments, with segment size of 105, 75 and 22 bp respectively. Among 300 samples, two kinds of alleles were detectable, which were A and C. There were three kinds of genotypes found in these 300 samples, exhibiting A/A wild type (127 bp, 75 bp), C/C homozygosis mutant (105, 75 and 22 bp) and A/C heterozygote mutant (127, 105, 75 and 22 bp) in genotypes (Figure S1). Among these 300 DNA samples, there were 276 cases of A/A wild type for CYP2C9*3 locus, which accounted for 92%. There were 22 cases of A/C heterozygote mutant, accounting for 7.3%. There were 2 cases of C/C homozygote mutant, accounting for 0.7%. The frequency of allele A was 95.67%, and that of allele C was 4.03%.

The DNA fragment of PCR and digesitive product at CYP2C9*3 locus was 22 bp. As it was too small, when the gel electrophoresis finished, this fragment has run out of the gelatin, this fragment could not be seen within the galatin. Only DNA fragments sized 127, 105 and 75 bp could be observed.

The segment size of CYP2C9*c_65 locus derived from the PCR and digestion in 300 DNA samples was all 371 bp (Figure S3). By using restrictive nuclease Hpa Ⅰ, when enzyme cutting site located at base G, 371 bp sized DNA fragment obtained from PCR was digested into two fragments, whose segment size was 317 and 54 bp respectively. When the enzyme cutting site located at base C, the DNA fragment of 371 bp could not digested by Hpa Ⅰ, leaving a single fragment of 371 bp. Among the 300 DNA samples, there were two kinds of alleles detectable, which were G and C. There were two kinds of genetypes found in these 3000 DNA samples, exhibiting G/G wild type and G/C heterozygote mutant (Figure S2). Among these 300 DNA samples, there were 281 cases showing G/G wild type, accounted for 93.7%. There were 19 cases showing heterozygote mutant, accounting for 6.3%. The frequency of allele G was 96.83%, and that of allele C was 3.17% (Figure S3).

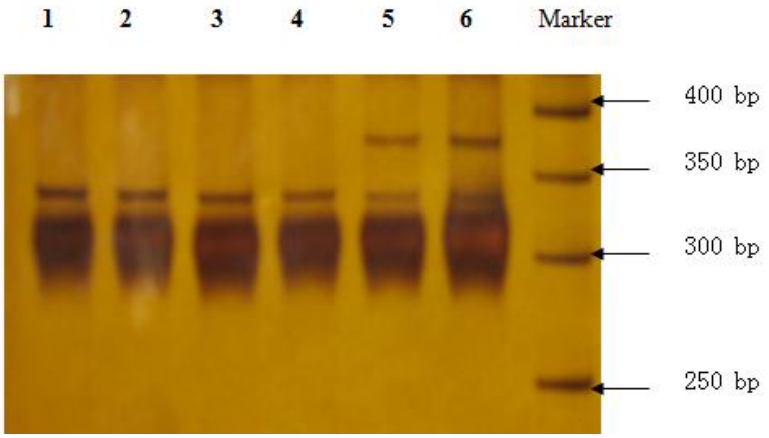

Figure S3. Showed genotypes of CYP2C9*c_65 locus. Number 1 to 4 were G/G of wild type (317 and 54 bp), Number 5-6 were heterozygote mutant (371, 317 and 54 bp).

Table 1. Hardy-Weinberg goodness of fit test of genotypes of CYP2C9*3 locus.

Frequency	A1/A1	A1/A2	A2/A2	χ^2	P

P		0.434 (>0.05)			0.714 (>0.05)	

DNA sequencing

Genetic analysis apparatus (3130 Genetic Analyzer, AB applied Biosystems) was used for sequencing the DNA fragments from PCR and restrictive nuclease digestion was conducted to confirm them as target DNA fragments. Results showed that sequencing outcome was in accordance with the standard DNA sequences of target DNA checked out from GeneBank.

Statistical analysis

Hardy-Weinbergbalance test (HWSIM) statistical analysis revealed that the observed number coincided well with the expected value in CYP2C9*3 and CYP2C9*c_65 locus (P>0.05), which was in accordance with the Hardy—Weinbergbalance law, suggesting that the DNA samples possessed group representativeness (Tables 1 and 2). Sex distribution of CYP2C9*3 and CYP2C9*c_65

P		0.263 (>0.05)			0.405 (>0.05)	

DISCUSSION

In the present study, only the population of patients subjected to the operation of cardiac valve replacement was investigated. Because, in this population, patients routinely administered Warfarin, which provides an appropriate opportunity to examine the correlationship of genotypes of special loci in CYP2C9 gene and Warfarin maintenance dosage. As for other diseases apart from cardiovascular disorders, such as diabetes, hypertension, were not involved in this study due to their independent with our study.

Influence of CYP2C9 gene mutation on Warfarin dosage in anticoagulant therapy and possible mechanism

The molecular mechanism of CYP2C9 gene polymorphism leading to metabolic defect of Warfarin lies on the base mutation, which results in alteration of sequences of DNA base, and then, amino acid replacement occurs, ultimately changes the catalytic activity of proteins, expressing as weak metabolic pattern and enzyme deficiency pattern. So far, researches involving in the correlation between CYP2C9 mutation and maintenance dosage of Warfrarin in anticoagulant therapy demonstrated that CYPC29 gene mutation could decrease the Warfarin metabolism. Therefore, patients with CYPC29 gene mutation needed relatively lower dosage of Warfarin.

Higashi et al. (2002) firstly reported that the correlation between genotype of CYP2C9 gene and anticoagulation or hemorrhage. Subsequently, Sconce et al. (2005) found mutation of CYP2C9*2 or CYP2C9*3 reduced the Warfarin dosage needed in patients subjected to anticogulantant therapy, and CYP2C9*3 mutation led to a more lage extent of Warfarin dosage reduction (30% reduced). There exists much variation of allele frequency in CYP2C9*2 and CYP2C9*3 loci among different races (Margaglione, 2000; Taube, 2000; Loebstein, 2001; Sanderson, 2005; Yu, 2004; Mizutani, 2003; Hong, 2005; Bae, 2005) as well. In White People, obvious ununiformity is commonly seen in the distribution of allele frequency of CYP2C9*2 gene in that the allele frequency ranges from 8 to 19% (Nakai, 2005; Scordo, 2001; Garcia-Martin, 2001). Higashi et al. (2002) reported CYP2C9 gene has high genetic polymorphism, especially in the mutation of CYP2C9*2 and CYP2C9*3, because the activity of enzymes encoded by them decreased 30 and 80% respectively when compared with that of wild type CYP2C9*1, which is the main cause of CYP2C9 mutation, leading to the lower dosage of Warfarin administered in patients with CYP2C9 mutation. Although the correlationship between CYP2C9*2 and/or CYP2C9*3 and Warfarin maintenance dose was involved in several studies by other authors, as for the correlation between CYP2C9*2 and/or CYP2C9*3 mutation and Warfarin maintenance dose in the Han people in China was few reported .Additionally, the crucial role of gene polymorphism of CYP2C9*2 and/or CYP2C9*3 in the intra-individual variation of Warfarin dose attracts more and more attention. Therefore, in this study, our finding that the influence of CYP2C9 gene polymorphism on the substrate drug metabolism has gene dosage effect sheds a new light on the personalized medicantion of Warfarin by applying Warfarin according to different genotypes of patients. Importantly, results from CYP2C9*3 locus study showed that the maintenance dose of Warfarin administered in anticoagulant therapy among the CYP2C9*3 genetypes exhibited: A/A wild type >A/C heterozygote>C/C homozygote, suggesting that patients carried with C/C mutation needed the lowest maintenance dose of Warfarin among the three genotypes found in this study. Our investigation is the first time to elucidate the conclusive correlationship between the mutatant in CYP2C9*3 gene locus and Warfarin maintenance dosage in Han people for clinical practice, providing a novel, useful and effective guaidance for Warfairin personalized medication according to different genotypes in different patients.

Correlationship between CYP2C9*c_65 locus mutation and Warfarin maintenance dosage

In the present study, CYP2C9*c_65 locus-genotypes and their corresponding distributed rates suggesting the mutation at CYP2C9*c_65 locus may not correlated with maintenance dosage of Warfarin. However, Chern et al.

(2006) found in Chinese Taiwanese population that the mutation in CYP2C9*c_65 locus could reduce the Warfarin dosage administered, and in patients carried c_65 heterozygote or homozygote only needed one half of conventional dosage of Warfarin. To further ascertain the conclusive correlation between mutation of CYP2C9*c_65 locus and the Warfarin maintenance, we investigate whether or not this correlation exist in the Han people of China. The results of ours and other authors above mentioned were much different, it is indicative that CYP2C9*c_65 mutation has obvious variation among different populations and races. At least until now, there are no definite evidence revealing CYP2C9*c_65 mutation has conclusive correlationship with Warfarin maintenance administered in anticoagulant therapy. This is another first report proposed by us from this study in Han people of China. We also found that there was no significant difference in genotype-distribution and allele frequency in CYP2C9*3 and CYP2C9 c_65 gene loci between male and female patients, suggesting CYP2C9 gene polymorphism had no definite correlation with gender variation.

Taken together, the maintenance dose of Warfarin administered in anticoagulant therapy among the CYP2C9*3 genotypes found in our experiment showed: A/A wild type> A/C heterozygote>C/C homozygote, suggesting that patients with C mutation need the lowest maintenance dose of Warfarin among the three genotypes found in this study. This will provide a conclusive and effective guidance for the Warfairin maintenance dose application according to different genotypes of patients. In future, intensive studies should focus on the correlation of more gene loci with Warfarin maintenance dose administered in the anticogulatant therapy and how to perform personalized medication of Warfarin in clinical practice.

ABBREVIATIONS

INR, International normalized ratio; **PT,** prothrombin time; **SNP,** single nucleotide polymorphism.

Scordo MG, Aklillu E, Yasar U, Dahl ML, Spina E, Ingelman-Sundberg M (2001). Genetic polymorphism of cytochrome P450 2C9 in a Caucasian an d a black African population. Br. J. Clin. Pharmacol. 52(4):447-450.

Taube J, Halsall D, Baglin T (2000). Influence of cytochrome P-450 CYP2C9 polymorphisms on warfarin sensitivity and risk of over-anticoagulation in patients on long-term treatment. Blood 96:1816-1819.

Yu BN, Luo CH, Wang D, Wang A, Li Z, Zhang W, Mo W, Zhou HH (2004). CYP2C9 allele variants in Chinese hypertension patients and healthy controls. Clin. Chim. Acta 348:57-61.

UPCOMING CONFERENCES

Human Genome Meeting (HGM) :: HGM 2014

The Biology Of Genomes May 6 - 10, 2014

Conferences and Advert

April 2014
Human Genome Meeting (HGM) :: HGM 2014

May 2014
The Biology Of Genomes May 6 - 10, 2014

September 2014
2nd International Conference on Genomics & Pharmacogenomics September 08-10, 2014 Raleigh, North Carolina, USA
