About JAT

The Journal of Accounting and Taxation (JAT) is a peer reviewed open access journal. The journal published monthly and covers all areas of Accounting and Taxation.

Open Access Policy

Open Access is a publication model that enables the dissemination of research articles to the global community without restriction through the internet. All articles published under open access can be accessed by anyone with internet connection.

The Journal of Accounting and Taxation is an Open Access journal. Abstracts and full texts of all articles published in this journal are freely accessible to everyone immediately after publication without any form of restriction.

Article License

All articles published by Journal of Accounting and Taxation are licensed under the [Creative Commons Attribution 4.0 International License](#). This permits anyone to copy, redistribute, remix, transmit and adapt the work provided the original work and source is appropriately cited. Citation should include the article DOI. The article license is displayed on the abstract page the following statement:

The Tax Cuts and Jobs Act (TCJA), effective on December 22, 2017, is the most comprehensive overhaul of the U.S. tax code in the last 30 years. Historically, when corporate tax rates are high, the interest deduction on debt is greater, thereby reducing firms' taxable income. However, with the new reforms significantly reducing corporate tax rates, the deductibility of the interest is no longer as favorable. In this paper, the effect of the TCJA on corporate debt ratios is analyzed. The authors hypothesize that corporate debt ratios have decreased since the passage of the TCJA. The results of the paper support our hypothesis that the long-term debt ratio is significantly negatively related to the implementation of the TCJA.

Key words: Tax cuts and jobs act; corporate tax; debt ratio; short-term debt; long-term debt.

INTRODUCTION

The Tax Cuts and Jobs Act (TCJA), which went into effect on December 22, 2017, reduced the top corporate tax rate from 35 to 21%, the largest cut in 30 years. In the United States, interest expenses are deductible for corporate tax purposes, while dividends must be paid out of after-tax corporate income. Therefore, the tax system favors debt financing over equity financing. The passage of the TCJA reduces the advantages of using debt to reduce taxes by lowering the overall corporate tax rate.

Meanwhile, the large amount of corporate debt has raised the attention of top U.S. regulators. As Jay Clayton, chairman of the Securities and Exchange Commission (SEC), pointed out, "In the United States, outstanding corporate debt stands at almost \$10 trillion, almost 50%

of GDP." "Those are numbers that should attract our attention" (Johnson, 2019). Therefore, it has become imperative to study how TCJA may affect the corporate debt policy.

Prior studies have discussed the question of whether taxes affect corporate financing decisions. Early papers such as Ang and Peterson (1986), Titman and Wessels (1988), and Fischer et al. (1989) all failed to find significant tax effects.

Later studies, such as Givoly et al. (1992) found a significant negative relation between leverage and corporate tax rate. Graham (1999) documented that firms with high tax rates have relatively high levels of debt. Gordon and Lee (2001) found that firms in the highest tax

*Corresponding author. E-mail: yu.zhang@msj.edu. Tel: 513-244-4437.

bracket have more debt than firms in the lowest tax bracket. However, none of the tax rates tested in prior studies was at the scales as regulated by TCJA.

LITERATURE REVIEW

Tax cuts and jobs act of 2017

The prototype of the U.S. corporate tax system debuted in 1894 (The Revenue Act of 1894). Various tax policies have had more or fewer amendments to the corporate tax laws since then. The current Code of Laws of the United States incorporates the corporate tax laws into Title 26, the Internal Revenue Code, formally the Internal Revenue Code of 1986, which is part of the Tax Reform Act of 1986 (TRA).

President George W. Bush made some changes to the Code's provisions in his Economic Growth and Tax Relief Reconciliation Act of 2001 and Jobs and Growth Tax Relief Reconciliation Act of 2003. Many provisions are related to individual taxes. For the corporate tax, only certain deductions were added or removed. Later, President Obama extended most of the Bush tax cuts in the 2010 Tax Relief Act and the American Taxpayer Relief Act of 2012. However, no major changes in the corporate tax rate have been made for nearly 30 years until the TCJA, which became effective, starting in 2018 (Tax Policy Center, 2022).

For individual taxes, TCJA only makes minor cuts, and the benefits will expire in 2025. However, for corporate taxes, the Act substantially decreases the top rate from 35 to 21%, and such change is made permanent.

Before the passing of the TCJA in December 2017, the U.S. has one of the highest corporate income tax rates among the Organization for Economic Co-operation and Development (OECD) economies (OECD, 2017). The model of Fehr et al. (2013) showed that capital favors low corporate tax countries. Therefore, in theory, TCJA should reduce incentives for businesses to move their tax base to low-tax jurisdictions and make the U.S. a more attractive location for foreign capital. The inflow of investment will also bring more job opportunities and households' income.

According to The White House (2019), TCJA has shown significant economic impacts, including an increase in GDP growth rate, higher business investment levels, increase in wage and salary income for households. Gale et al. (2018) summarized the five major consequences of TCJA: 1). Boost the economy in the short term but has little effect on long-term growth; 2). Reduce federal income; 3). Enlarge inequality in the distribution of after-tax income; 4). Simplify the tax filing process in some ways but generate new complexities in others; 5). Reduce coverage of health care and charitable donations.

Empirical studies on how TCJA affects each individual,

and society as a whole found mixed results. Page et al. (2017) did a macroeconomic analysis of TCJA and found that the law will raise the US GDP by 0.8% in 2018 and have no impact on GDP in 2027 or 2037. The resulting rise in taxable income will minimize revenue loss resulting from the Act from 2018 to 2027 by \$186 billion (around 13%).

In terms of the stock market reaction to the TCJA, Wagner et al. (2018) found that stocks' prices responded to the difference between the original and revised expectations. High-tax companies benefited substantially from the bill's introduction in the United States House of Representatives to the final passage (November 2 to December 22, 2017).

However, because of the one-time repatriation tax on profits in overseas subsidiaries required by the TCJA, multinationals suffered significantly. Overall, the stock price movements show that the market reacted positively to lower expected corporate taxes.

Rader (2020) evaluated the direct and indirect effect of TCJA on the U.S. real estate market and concluded that although TCJA has a negative impact on high tax states; it pushed asset markets to new highs, generating a demographic change that may have future political implications. The paper also discussed the creation of opportunity zones, which is part of the TCJA. The main finding is that the opportunity zones program has positive intentions but lacks sufficient accountability measurements.

Because TCJA drastically reduced the corporate income tax rate, it encouraged firms to increase their pension contributions in 2017, the year before TCJA became effective, to take advantage of tax deductions at a higher rate.

Gaertner et al. (2018) found that firms raised their defined benefit pension contributions by an average of 27% in 2017 relative to previous years. Firms with high deferred tax assets increased four times more than firms with low deferred tax asset levels. In addition, firms with more financial reporting pressure drive the result.

Besides reducing the corporate income tax rate, TCJA also limited interest deductibility for certain firms. Yu (2020) argue that this element of the reform will likely destroy horizontal equity and economic neutrality. This is because limiting the amount of interest expense that corporations can deduct while allowing the entire lease expense or cost of goods sold to be deducted would be unfair to firms financing themselves through debt than through leasing. If a corporation needs to acquire equipment, it should be indifferent between borrowing money to purchase the equipment or leasing it. Carrizosa et al. (2020) find that 257 U.S. firms are affected by the limited interest deductibility component of TCJA, and these firms decrease book leverage by 2.9% of total assets. To increase the generalizability of this paper, our paper focuses on the overall impact of the corporate income tax rate reduction of TCJA, including firms that

are subject to interest deductibility limitations.

Debt ratios

A company's debt ratio shows whether it has loans and how its credit financing is compared to its assets. The basic form of debt ratio is calculated as dividing total debt by total assets. Higher debt ratios suggest higher degrees of debt financing and greater risk associated with firms' operations because debt ultimately needs to be repaid with interest.

Debt ratios are used to describe a company's financial health. However, there is no clear indicator of how much the debt ratio is good or bad. It depends on the company's industrial sector, size, and development stage.

Prior research regarding corporate debt ratios investigated what factors may affect debt ratios and how debt ratios further affect a company's operation.

Stiglitz (1972) used mathematical models to show that firms with a high possibility of bankruptcy may choose a low debt-equity ratio to avoid failures. In the paper, he also mentioned that some take-overs and mergers should be included in the same category as bankruptcy because those methods of disappearance have lower costs than actual bankruptcy.

Kim and Sorensen (1986) examined several determinants of debt ratios. They used long-term debt divided by total capitalization in book value as a measure of debt. They concluded that firms whose equity ownership is concentrated among insiders make more use of debt than firms that are owned by many shareholders. That is easy to understand because debt will not dilute insiders' control of the firm. They also documented several factors, such as growth rate and operating risk that may affect firms' debt usage.

McConnell and Servaes (1995) empirically investigated the relation between firms' value and leverage. They used total debt divided by total assets to measure leverage and found that the relationship depends on growth levels. For high-growth firms, firm value is negatively correlated with leverage, whereas for low-growth firms, corporate value is positively correlated with leverage.

Aivazian et al. (2005) used information on Canadian publicly traded firms to analyze the effect of financial leverage on firms' investment decisions. Their measure of financial leverage is the book value of total liabilities divided by the book value of total assets. The result shows that leverage is negatively related to investment. For companies with low growth opportunities, this negative impact is significantly greater than for those with high growth potential.

D'Mello et al. (2018) examined shareholders' views of corporate debt. They found that U.S. companies' shareholders value an extra dollar in long-term debt to be \$0.28 on firms' value between 1980 and 2014. This

indicates that American investors believe the cost of increasing debt exceeds the benefits and companies are overleveraged.

Firms' choices of debt ratios are affected by many factors. Although debt is considered to be the lowest cost source of capital, excessive borrowing can lead to bankruptcy risks.

Contribution to literature

To empirically test how TCJA affects firms' debt policies, this paper analyzes the data from WRDS firm-level Financial Ratios Suite and COMPUSTAT right before and after the passage of TCJA. A binary variable was created, "new_policy", coded with a value of 1 if the data are in 2018 and 0 if in 2017. The authors first run the univariate tests to check the correlations. The total debt ratio and the long-term debt ratios are negatively related to new_policy at the 5% level, supporting their hypotheses.

Multivariate analyses were then run by adding other factors that affect firms' borrowing into the regression models. The correlation between new_policy and long-term debt ratio is consistently negative. However, the authors did not find a negative relation between the new_policy dummy and the total debt ratio or the short-term debt ratio. Liabilities instead of debt were used to construct the dependent variables; the same results were found. This paper contributes to the literature in the following ways:

First, several debt ratios were examined. Besides the total ratio, which is extensively studied, the authors also investigated how firms' use of short- and long-term debts is affected by TCJA. This paper enriches the literature on how tax-cut effects shape short- vs. long-term debt ratios.

Second, the empirical literature on corporate debt choice has so far not been very successful in identifying the importance of the tax advantage of debt (Huizinga et al., 2008). This study examines the issue in the new policy context and shows that overall; the tax cut reduced firms' use of long-term debt.

Finally, our study adds to the debate about whether TCJA is good or bad for society. We show that companies, in general, react to the policy by reducing their debts for the tax-shield purpose, which may reduce firms' risk in the long run.

The remainder of the paper is organized as follows. Section 2 presents the study hypotheses. Section 3 describes the data and methodology; Section 4 discusses empirical results, and Section 5 concludes.

Hypothesis development

Companies generally have two ways to raise funds: one is to borrow money, and the other is to issue stocks. In

the United States, debt has an advantage over equity capital because payments to debt holders are deductible for corporate tax purposes. In contrast, payments to shareholders, that is, dividends, have to be paid out of net-of-tax corporate income.

As mentioned earlier, the biggest tax cut before 2017 is the TRA of 1986, which reduced the top corporate tax rate from 46 to 34%. Givoly et al. (1992) examined the relationship between leverage and tax-related variables for a sample of U.S. firms in the years surrounding the passage of the TRA. Leverage is defined in the paper as the ratio of debt to the sum of debt and equity. Their major finding is that the corporate tax rate is negatively and significantly related to the leverage ratio.

In addition, before the enactment of the TCJA, the U.S. tax system used a tiered tax rate ranging from 15% to as high as 35%. Because of the difference in incorporate tax rates, Gordon and Lee (2001) found that the largest firms with a 35% tax rate have 8% more debt than smaller firms whose tax rate is only 15%. Graham et al. (1998) found a similar result that there is a positive relationship between debt levels and tax rates.

Studies in other countries also show a positive correlation between debt usage and taxes. For example, Shum (1996) tested the corporate debt policy in Canada from 1979 to 1989 and found that the use of debt increases when the tax is higher. By examining firms in 39 developed and developing countries, Fan et al. (2012) found that firms tend to use more debt in countries where the corporate tax rates are higher. De and Nigro (2012) investigated the relation between debt and tax in a European context. Their results suggest that corporate income taxation is positively related to leverage. They defined leverage as the ratio of debt to the sum of debt and equity.

As can be seen, prior literature suggests that when tax rates are high, firms borrow money and pay interest on debts to reduce their taxable incomes. However, TCJA lowered the maximum corporate tax rate from 35 to 21%, and the tax deductibility of the interest is no longer as favorable. Therefore, we made our first hypothesis:

H1: Compared to 2017, there is a significant total debt ratio reduction in 2018 after implementing the TCJA

Debt maturity is an important part of a company's financial policy. For most companies, the question is not only how much debt, but also how long will the debt become due. In accounting, total debt is classified into long-term and short-term debt. Short-term debt is payable within one year, while long-term debt has a maturity longer than that.

Generally, short-term debt is used to make up temporary shortfalls in cash flow. Interest rates on short-term debt are lower than rates for long-term debt because lenders require a higher premium for taking more risks since payments are extended for several years. Firms are less likely to use short-term debt to

avoid taxes because of the low interest rate and the primary purpose of temporarily alleviating the current cash flow problem. Thus, we have the following hypothesis:

H2: Compared to 2017, there is no significant short-term debt ratio reduction in 2018 after implementing the TCJA

On the other hand, firms pay a higher interest rate on the long-term debt, and they may use the long-term debt for things other than solving the short-term cash flow issue. This makes the long-term debt a perfect instrument to reduce taxes. Such usage may be discouraged because of TCJA. The argument leads to our last hypothesis:

H3: Compared to 2017, there is a significant long-term debt ratio reduction in 2018 after implementing the TCJA

DATA AND METHODOLOGY

Debt ratios are extracted from WRDS firm-level Financial Ratios Suite. Some ratios were also calculated using the data from COMPUSTAT if they are not available in the Financial Ratios Suite. COMPUSTAT data contain companies from the NYSE, NYSE American, NASDAQ, and NYSE Arca exchanges. The authors deleted those firms, with debt ratios (total debt/total assets), larger than one because they have negative equity. To avoid results driven by outliers, all numerical data are trimmed at the 1% level. The final sample consists of 3,220 firm-year observations which include 1853 distinct firms from 55 industries classified by the two-digit SIC code. The large number of industry classifications included in this study suggests that the sample is a good representation of the population. The summary statistics of the sample is presented in Table 1.

To investigate how corporate choices of debt ratios are affected by the TCJA, a binary variable, *new_policy* was created. It is coded with a value of 1 if the data are in the year 2018 and 0 if in 2017. We expect to see a negative correlation between *new_policy* and the debt ratio. Run univariate test was first used to check the correlations. The results are tabulated in Table 2.

Prior research documents several factors that affect a firm's debt policy. To control the impact of those variables, we then run multivariate regression models to test the relation between *new_policy* and debt ratios.

First, large firms have lower costs of financial distress and suffer lower information costs associated with borrowing (Graham, 1999). The natural logarithm of total assets was used as the proxy for firm size. Second, a firm with extensive collateral should use more lease financing and is more likely to borrow on favorable terms (Graham et al., 1998; Huizinga et al., 2008). In this paper, collateral is defined as the ratio of net property, plant, and equipment divided by total assets. Third, more profitable firms have better access to the credit market. Following Krämer (2015), we measure profitability as the ratio of earnings before interest and taxes to total assets. Fourth, Longstaff and Strebulaev (2014) documented that liquidity affects debt ratios. Illiquid firms face higher borrowing costs. Therefore, the cash and current ratios in the model were included. The cash ratio is the ratio of cash to total assets. The current ratio is the ratio of current assets to total assets, where current assets include cash, accounts receivable, and inventories. Fifth, MacKie-Mason (1988) used tax loss carry forward and investment tax credit to capture other tax effects on corporate financing decisions.

We also include these two variables in the study. Moreover, growth has been documented to affect debt ratio (McConnell and

Table 1. Sample statistics.

| SDR | 3220 | 0.05 | 0.01 | 0.00 | 0.03 | 0.47 |
| LDR | 3220 | 0.22 | 0.18 | 0.00 | 0.34 | 0.25 |

Source: Authors

Servaes, 1995; Aivazian et al., 2005). As suggested in Rajan et al. (1995), Market-to-Book (MB) ratio was used to measure growth opportunities. Finally, to control the industry fixed effects, two-digit industry dummies are included in the model.

The following multiple regression model was used to observe the statistical significance of new_policy and other control variables on debt ratios.

$$TDR = \alpha + \beta_1 \text{New_policy} + \beta_2 \text{Size} + \beta_3 \text{Collateral} + \beta_4 \text{Profit} + \beta_5 \text{Cash} + \beta_6 \text{Current} + \beta_7 \text{LC} + \beta_8 \text{ITC} + \beta_9 \text{Growth} + \sum \beta_k \text{IND} + \epsilon \quad (1)$$

Where:

TDR = Total debt ratio, calculated as total debt divided by total assets (DLC+DLTT/AT); New_policy = 1 if the data are in the year 2018 and 0 if in 2017; Size = The natural logarithm of total assets (AT); Collateral= The ratio of net property, plant, and equipment divided by total assets (PPEGT/AT); Profit = The ratio of earnings before interest and taxes to total assets (EBIT/AT); Cash = The ratio of cash to total assets (CHE/AT); Current = The ratio of current assets to total assets, where current assets include cash, accounts receivable, and inventories (ACT/AT); LC = Tax loss carry forward divided by net sales (TLCF/SALE); ITC = Investment tax credits divided by net sales (ITCB/SALE); Growth = Market value of equity to book value of equity (CEQ/PRCC_C*CSHO); IND = 2-digit industry dummies.

Under H1, we expect the sign of the coefficient on new_policy to be negative, indicating that overall, firms' total debt ratios in 2018 were lower than that in 2017.

The authors repeat regression (1) using SDR and LDR each as the dependent variable. All the control variables remain the same.

Where:

SDR = Short-term debt ratio, calculated as short-term debt divided by total assets (DLC/AT); LDR = Long-term debt ratio, calculated as long-term debt divided by total assets (DLTT/AT). Compustat variable names are reported in parentheses.

If H2 and H3 hold true, we should see no significant coefficient on new_policy when SDR is used as the dependent variable, but a significant negative coefficient on new_policy when we use LDR as the dependent variable.

RESULTS AND DISCUSSION

Table 1 reports the summary statistics of data. There are 3,220 observations with non-missing values for both dependent and control variables. The mean of new_policy is 0.48, which means that 48% of observations are in 2018, after the enactment of TCJA. The average natural logarithm of firms' total assets is 6.56. The mean of Collateral shows that, on average, sample firms have 51% of their total assets to be net property, plant, and equipment. The mean profit of -0.04 indicates a loss. The average cash ratio is 0.16, while the average current ratio is 0.38. The sample firms have a positive book tax loss carry forward. However, they do not seem to have investment tax credits. The average MB ratio is 4.31. The sample firms have an average total debt ratio of 27%, consisting of a 5% short-term debt ratio and a 22% long-term debt ratio.

Table 2 shows the Spearman correlation coefficients. As predicted, new_policy is negatively correlated with TDR at 5% significance level (correlation coefficient = -0.04 and p-value = 0.03), which indicates that the total debt ratio is reduced after the new policy was passed. The correlation coefficient between new_policy and SDR is -0.01. However, this relation is not significant (p-value = 0.47). The correlation between the long-term debt ratio and new_policy is significant at 5% level (correlation coefficient = -0.03 and p-value = 0.05). The correlation coefficients support our hypothesis that compared to 2017, there is a significant total or long-term debt ratio reduction overall in 2018 after the implementation of TCJA (H1 and H3). For the short-term debt ratio, there is no significant reduction (H2).

The results of the multivariate analysis are presented in Table 3. Model 1 through Model 3 provides regression results using TDR, SDR, and LDR as the dependent variable, respectively. For Model 1, when controlling

The probability that each correlation coefficient is different from zero (p-value) is reported under the correlation. The reported P-values are for double-tailed tests. Pearson correlations provide similar results and are not tabulated.

Source: Authors

for other variables that affect companies' debt policies, the coefficient on our primary variable of interest, *new_policy*, is no longer significant (coefficient =0.00 and p-value =0.89). Total debt can be divided into short-term and long-term debts. When we analyze the multivariate models of short-term and long-term debt ratios separately, it was found that there is a significant positive

relation between *new_policy* and SDR. This result is contrary to expectations. However, when we look at the model for long-term debt ratio, we see a significant negative relation between LDR and *new_policy* (coefficient =-0.03 and p-value =0.02), which supports our H3.

Taken together, the insignificant result of the total debt ratio appears to be driven by the positive

correlation of short-term debt. Short-term debt is increased if other factors that affect borrowing are controlled for. This result is not surprising given the fact that long-term debt decreased because the benefit of the interest tax deduction diminished after the TCJA. Instead, firms may choose short-term loans with lower interest rates to meet their cash needs.

Source: Authors

Table 3 also shows several significant control variable coefficients. Consistent with Graham (1999), size is positively related to debt ratios because larger firms easily borrow money. Collateral also has a positive sign. According to Huizinga et al. (2008), a firm with extensive collateral can borrow on favorable terms. Both Profit and Cash are negatively related to debt ratios, suggesting that profitable firms and firms with more cash in hand have fewer loans.

Firms with higher current ratios borrow more short-term debts but less long-term debts, which is consistent with the notion that firms attempt to match the maturities of their assets and liabilities (Myers, 1977). Loss carry forward deduction is negatively related to debt ratios, indicating that firms may use different tax deductions as a substitution.

Besides using debt, many researchers have used liabilities as the numerator when calculating debt ratios (Aivazian et al., 2005; Longstaff and Strebulaev, 2014). To assess the robustness of the authors' results, they also use a second measure of debt ratios. TLR, SLR, and LLR are used as the dependent variable to run regression (1).

Where:

TLR = Total liabilities divided by total assets (LT/AT);
 SLR = Short-term liabilities divided by total assets (LCT/AT); LLR = Long-term liabilities divided by total assets ((LT-LCT)/AT). Compustat variable names are reported in parentheses.

The results are reported in Table 4. New_policy is not

significantly related to TLR at any significance level. But it is positively related to SLR at the 5% significance level and negatively related to LLR at the 1% significance level. This finding corroborates our earlier results in Table 3 where we find no significant coefficient for total debt ratio, but a positive and a negative coefficient for short-term debt ratio and long-term debt ratio, respectively. We verify that our reached results are not driven by the way debt ratios are calculated. The multivariate analysis supports H3, but not H1 and H2.

Additional analyses¹

The research objective in this study is to test whether TCJA's corporate tax policy has positive effects on firms in general. All the hypotheses are supported. The next question we may ask is whether this new policy is effective at the individual firm level. To test how the changes in debt ratios for the same firms are affected by the TCJA, we calculate the two-year average debt ratio changes before and after the new policy and use the variables as the dependent variables in the regression analyses. The authors' new sample period is from 2014 to 2019. They include the years 2014 and 2015 to calculate the changes in debt ratios before the TCJA.

Following Graham and Tucker (2006) and Platikanova (2017), a few more control variables in the regression

¹ We appreciate the anonymous reviewers' recommendation to conduct these tests.

models were included. Cashflow and ROA are used as proxies for liquidity risk which affects borrowers' preference for short-term debt. Dividend distributions, capital expenditures, and R and D expenses are used to control firms' investment opportunities which affect firms' financing decisions. Firms' propensity to use debt and their potential to engage in tax evasion are likely to be influenced by foreign activities and intangible assets. We also control these two variables.

In addition, the presence of net operating losses before TCJA was used as a proxy for low marginal tax rates (MTRs). We then interact MTRs with New_policy. It was expected that the coefficient on the interaction would be opposite to the sign on New_policy because firms with low pre-TCJA MTRs were likely affected less by the corporate tax rate change since they already faced lower tax rates than companies with higher pre-TCJA MTRs.

There are two approaches for managers to lower companies' debt ratios. The first way is to buy back their debt on the open market. Second, increasing retained earnings while maintaining the same level of debt can also reduce debt ratios.

Therefore, we included retained earnings as a control variable to test whether increased retained earnings can be a reason for the changes in debt ratios.

Since short-term debt ratios are typically influenced by net working capital needs, a matching of assets and liabilities was included in the working capital as a control variable in the short-term debt ratio model. On the other hand, long-term debt ratios are typically influenced by investments in long-term fixed assets. Investments in long-term fixed assets should be included as a control

variable in the long-term debt ratio model. However, the proxy for collateral is calculated using the long-term fixed asset data and can serve the same purpose.

The following new multiple regression models were used to test the new policy's effects at the individual firm level:

$$\Delta TDR = \alpha + \beta_1 \text{New_policy} + \beta_2 \text{Size} + \beta_3 \text{Collateral} + \beta_4 \text{WC} + \beta_5 \text{Profit} + \beta_6 \text{Cash} + \beta_7 \text{Current} + \beta_8 \text{Growth} + \beta_9 \text{DIV} + \beta_{10} \text{ROA} + \beta_{11} \text{CASHFLOWS} + \beta_{12} \text{EXPENDITURE} + \beta_{13} \text{FOREIGN} + \beta_{14} \text{INTANGIBLES} + \beta_{15} \text{RD} + \beta_{16} \text{LMTR} + \beta_{17} \text{New_policy} * \text{LMTR} + \beta_{18} \text{RE} + \sum \beta_k \text{IND} + \varepsilon \quad (2)$$

$$\Delta SDR = \alpha + \beta_1 \text{New_policy} + \beta_2 \text{Size} + \beta_3 \text{WC} + \beta_4 \text{Profit} + \beta_5 \text{Cash} + \beta_6 \text{Current} + \beta_7 \text{Growth} + \beta_8 \text{DIV} + \beta_9 \text{ROA} + \beta_{10} \text{CASHFLOWS} + \beta_{11} \text{EXPENDITURE} + \beta_{12} \text{FOREIGN} + \beta_{13} \text{INTANGIBLES} + \beta_{14} \text{RD} + \beta_{15} \text{LMTR} + \beta_{16} \text{New_policy} * \text{LMTR} + \beta_{17} \text{RE} + \sum \beta_k \text{IND} + \varepsilon \quad (3)$$

$$\Delta LDR = \alpha + \beta_1 \text{New_policy} + \beta_2 \text{Size} + \beta_3 \text{Collateral} + \beta_4 \text{Profit} + \beta_5 \text{Cash} + \beta_6 \text{Current} + \beta_7 \text{Growth} + \beta_8 \text{DIV} + \beta_9 \text{ROA} + \beta_{10} \text{CASHFLOWS} + \beta_{11} \text{EXPENDITURE} + \beta_{12} \text{FOREIGN} + \beta_{13} \text{INTANGIBLES} + \beta_{14} \text{RD} + \beta_{15} \text{LMTR} + \beta_{16} \text{New_policy} * \text{LMTR} + \beta_{17} \text{RE} + \sum \beta_k \text{IND} + \varepsilon \quad (4)$$

Where:

ΔTDR = Two-year average total debt ratio changes before and after the new policy; ΔSDR = Two-year average short-term debt ratio changes before and after the new policy; ΔLDR = Two-year average long-term debt ratio changes before and after the new policy; WC =

Working capital, calculated as current assets (ACT) minus current liabilities (LCT), scaled by total assets (AT); DIV = 1 if a firm pays dividends (DVC), and 0 otherwise; ROA = Earnings before interest, taxes, depreciation, and amortization (EBITDA) to total assets (AT); CASHFLOWS = Income before extraordinary items (IBADJ) plus depreciation (DP) to total assets (AT); EXPENDITURE = Capital expenditures (CAPX) to total assets (AT); FOREIGN = Foreign pre-tax income (PIFO) to total assets (AT); INTANGIBLES = Intangible assets (INTAN) to total assets (AT); RD = Research and development expenditures (XRD) to total assets (AT); LMTR = 1 if a firm has tax loss carryforward (TLCF) in 2017, and 0 otherwise; RE = Retained earnings (RE) to total assets (AT). Compustat variable names are reported in parentheses.

All other variables are defined the same as in regression (1). LC is dropped from the model because we use the same variable to define LMTR. ITC is also dropped because only a small number of exceptional credits provided by foreign jurisdictions or some old ITC carryovers are included within the sample period of this study.

Table 5 reports the sample statistics for the variable of interest and dependent variables. The authors deleted

any firm years with missing values of dependent and control variables. Our final sample consists of 1876 firm-year observations with 938 distinct firms. As we can see, the mean and median changes in debt ratios are all very tiny, compared to the absolute value of debt ratios in Table 1.

Spearman correlation coefficients are reported in Table 6. Pearson correlations provide similar results and are not tabulated. In terms of changes in debt ratios, New_policy is not significantly related to either the change in the total debt ratio or the change in the long-term debt ratio. However, the sign of the correlation coefficient on the change in the long-term debt ratio is negative as we expected. The insignificance may be because the changes, in contrast to absolute values, are very small numbers, making it challenging to detect a clear association. Same as the previous tests, new_policy is significantly and positively related to the change in the short-term debt ratio.

The results of the multivariate analysis for the changes in debt ratios are presented in Table 7. When we control the factors that may affect firms' financing decisions, the coefficients on New_policy are negative as expected, but not significant for the change in total debt ratio (t-Statistic= -0.81) and the change in long-term debt ratio (t-

Statistic= -1.41). A significant and positive coefficient on New_policy for the change in the short-term debt ratio is still seen.

In terms of the control variables, collateral, measured by using long-term fixed assets, has a positive effect on the change in the long-term debt ratio. However, this coefficient is not significant. On the other hand, the working capital variable

(WC) has a significant and negative coefficient in the Δ SDR model, suggesting that a company's short-term debt ratio will decrease if it has a high level of working capital. LMTR and its interaction with New_policy do not give us any significant coefficients. Again, as can be seen in Table 5, the changes in debt ratios are trivial, which may be the reason why we cannot see any significant

results here at the individual firm level.

Conclusion

No matter how much criticism it has received, the TCJA of 2017 is the largest reform of the U.S. corporate tax law in the past 30 years. The new

law brought great benefits to U.S. companies, with the highest tax rate reduced from 35 to 21%.

Interest payments on debt have been documented as a tax shield, which firms frequently use to avoid taxes (Stiglitz, 1986; Desai and Dharmapala, 2009). The enormous reduction in the corporate tax rate makes the use of debt less desirable to lower taxes. Bank of America-Merrill Lynch asked more than 300 managers at major US companies what they would do with a corporate tax cut. The No.1 reply is to pay down debt (Long, 2019). In this paper, the empirical test was used to show that the executives did what they responded to in the survey.

Although many opponents believe that TCJA has not achieved the promised benefits, the research found that TCJA effectively reduces companies' debt in general. The reduction of debt, especially the debt solely for tax purposes, is good for companies in the long run. According to Castanias (1983), when businesses do not have an incentive to increase debt because of tax benefits, they may choose a borrowing strategy that is more optimal in terms of increasing firms' overall value. A low debt ratio reduces both transaction costs and liquidation costs.

This paper has some implications for both regulators and investors. For policymakers, it was found that firms react to the tax cut by reducing their debts, which further reduces their risks. This may help build a healthier financing system as we know that the 2008 financial crisis is primarily due to excessive use of debt (Russo and Katzel, 2010). For investors, it was shown that reducing corporate risk-taking behavior will benefit them in the long run.

The limitation of the paper is that we can only use the data for two years surrounding the effective date of the TCJA due to the COVID pandemic. The effect may not be fully reflected because firms need time to adjust their policies and react to the new rule.

Full Length Research Paper

Compliance during the COVID-19 pandemic: Knowledge of tax relaxation, completeness of documents and their socialisation

Yayuk Ngesti Rahayu

Master of Management Study Program, Postgraduate, Wisnuwardhana University Malang , East Java, Indonesia.

Received 16 November, 2022; Accepted 17 January, 2023

The study aimed to determine the role of document completeness as a moderating variable in the relationship between knowledge of tax relaxation and taxpayer compliance and the relationship between tax relaxation policy socialisation and Small and Medium Enterprises (SMEs) taxpayer compliance registered at the North Malang - East Java - Indonesia Primary Tax Service Office. The moderation test in this study used WarpPLS, with a unit of analysis of 158 SMEs with micro business groups 62.1% worked all day, 29% worked during the day and 8.9% worked at night. This research was conducted by combining experiments and survey strategies using questionnaires. Moderation test using WarpPLS to determine how much the document completeness variable strengthened the relationship between tax relaxation knowledge and policy outreach to SMEs taxpayer compliance applying for tax relaxation. The results showed that business legality, bookkeeping, financial reports and transcripts of financial report elements improved the relationship between tax relaxation knowledge and policy outreach to SMEs taxpayer compliance during the Covid-19 pandemic. To get maximum results, the R-Squared results make it possible to add variables that have not been included in this study. To get maximum research results, the next researcher should add other variables outside the variables studied.

Key words: Knowledge, socialisation, completeness of documents, compliance.

INTRODUCTION

Why must Small and Medium Enterprises (SMEs) comply with their tax obligations? Because taxes have an important function in the economic system of a country. First, taxes supply government funds for development, both central and nearby governments. Both taxes function as a device that regulates government policies in the socio-economic field. The proportion of tax income has improved appreciably, each nominal and as a

share of the total kingdom revenue.

On the other hand, the taxpayers' share is very small compared to Indonesia's total population. This aspect shows that the Indonesian people's focus on paying taxes is low. SMEs have a sizeable role in the country's monetary growth. The contribution of SMEs to the Indonesian economic system is capable of soaking up 97% of the complete workforce and acquiring up to 60.4%

E-mail: yayukngesti@wisnuwardhana.ac.id. Tel: 081217133660.

Author(s) agree that this article remain permanently open access under the terms of the [Creative Commons Attribution License 4.0 International License](https://creativecommons.org/licenses/by/4.0/)

of the total investment. Based on records from the Directorate General of Taxes, and the Ministry of Finance, the contribution of SMEs to the Gross Domestic Product reached 61.41%. MSMEs managed to absorb almost 97% of the worldwide group of workers and in terms of the number of business units, 99.99% of the complete commercial enterprise actors. In Indonesia, it is around 62.9 million units, while massive companies are solely 5,400 devices (0.01%). Therefore, the Indonesian financial system is growing hastily thru the SMEs sector.

Highlighting the consequences of a survey via the Malang City Cooperative Industry and Trade Office in 2021 that the contribution of SMEs to the East Java economic system that Malang City is in the fifth location out of 38 cities and regencies in East Java whilst the first area is Surabaya City, Sidoarjo City, Pasuruan City, Gresik City. The contribution of SMEs in Malang City reached 69.87 of 57.25% of East Java's Gross Regional Domestic Product from a whole of 113.132 SMEs unfolded over five sub-districts and fifty-seven wards. Of the five sub-districts in Malang City, the Lowokwaru sub-district is the most densely populated-because various public and private universities are in the area, so MSMEs in the place thrives. However, Many SMEs do not have enterprise legality starting from the Business license, Certificate of Company Registration, Micro Small Business License, Industrial Business Permit, Deed of Business Establishment, Principle Permit, and Stock Keeping Unit. By having a commercial enterprise legality or business license, MSMEs can use it for the capacity of criminal protection, the potential of promotion, and proof of compliance with the rule of law, making it simpler to get an undertaking and facilitate enterprise development.

The massive effect of Covid-19 pandemic that used to be felt through SMEs were caused by a reduction in the stage of public consumption due to the policy of enforcement of the community activity restrictions policy beginning from self-isolation work from home. Ensuring a limit on the personnel involved in production activities, limiting business which reasons a limit in income turnover to shut its operational activities. One of the impacts of SMEs experienced was a reduction in earnings and turnover, and economic constraints affected workers due to the fact decrease in operational things to do regularly ended with a reduction in the quantity of personnel (Utami, 2021).

According to the government's fiscal policy throughout the Covid-19 pandemic were extra focused on three things. First, a centre of attention on efforts to address the public fitness aspect. Fiscal units for the fitness sector have to be a problem to forestall transmission, monitoring, care, availability of facilities, and therapy research. Second, fiscal units need to play a position in supporting events affected with the aid of the monetary downturn. Third, they want to motivate complete demand (aggregate demand). One of the most felt influences of the COVID-19 pandemic is Micro, Small and Medium

Enterprises, due to the fact that Micro, Small, and Medium Enterprises have a sizable contribution to employment and growth of job opportunities because this group has verified to be capable withstanding quite a number sorts of monetary shocks. In China (Liu, 2021), Nigeria (Aladejebi, 2018) and Korea (Choi et al., 2022) determined three effects of economic severity throughout the Covid-19 pandemic in Korea divided into three scenarios: a reduction in gross domestic product, an make bigger in government spending and an expansion in tax income; in Indonesia (Noviyanti and Azam, 2021; Listiyowati et al., 2021; Zulfikar et al., 2021). The influence of the Covid-19 pandemic on micro, small and medium commercial enterprise taxpayers who take gain from tax incentives (Budiman et al., 2020; Wardani and Wati, 2018; Sitorus, 2021). The compliance of taxpayers in carrying out tax duties required with the aid of the use of the law is formal compliance and material compliance. cloth compliance is greatly influenced by the skill of expertise of taxpayers in calculating methods, tax topics and objects, methods for filing objections and the lack of archives when enacting insurance plan policies (Rahayu et al., 2017). Then again there are a few forms of compliance per the community's behavioural intentions, especially voluntary compliance and compelled compliance. Previous researchers who studied formal, material, voluntary and enforced compliance had been carried out with the aid of way of (Alm et al., 2020; Rahayu et al., 2017; Müller and Rau, 2021).

Some of the limitations confronted with the resource of MSMEs when they pick to get tax incentives: a) lack of statistics of taxpayers about tax rest (Kilo et al., 2022) now no longer having a Tax ID vast variety or to register for a Tax ID number, however the requirement to register Tax ID range for SMEs is to have a business permit, company registration certificate, micro and small business permit, industrial business permit, business establishment deed, principle permit; b) task gaining access to and reaching choices throughout the large-scale social restrictions; c) data asymmetry related to tax incentive insurance plan policies at companies backyard the Directorate General of Taxes (DGT), e) granting a Letter of request for explanation of data and/or informations and requests for corrections that are however being carried out via skill of DGT, it is quintessential that this look up is carried out to gain records greater accurate and to reap preferences to enhance tax compliance for SMEs.

LITERATURE REVIEW

The impact of the Covid-19 pandemic has resulted in the weakening of the foundations of the Indonesian economy. To decrease the unfolding of the virus, the government issued insurance policies ranging from imposing restrictions on community things to do to large-

scale social restrictions. This coverage influences the survival of micro, small and medium agencies ensuing in a decrease in sales turnover, to termination of employment, in particular commercial enterprise actors who are not contributors of on-line couriers such as GoFood and GrabFood.

The decline in turnover resulted in micro, small and medium enterprises being unable to pay all operational charges and worker salaries, so there have been many employee reductions. The tax rest policy or the provision of tax incentives is given through the authorities as a shape of help to recover throughout the pandemic. Tax incentives are policies carried out by way of the government in the shape of lowering the tax burden borne by taxpayers or taxes borne by way of the government.

Tax incentives can make public spending bigger, because the rate of a product in the market will be relatively lower due to tax incentives (Amah et al., 2021). Tax relaxation provides tax incentives aimed at investors, business actors and individuals. This coverage is predicted to grant convenience and encourage taxpayers to comply with their tax duties throughout the pandemic and in the future (Guo and Shi, 2021). Two tax incentives are enforced in Indonesia: Tax holiday is a facility to supply a reduction in company earnings tax, and Tax allowance is an income tax facility for investment in positive agencies and regions (Warsito and Samputra, 2021). The policy of imparting tax incentives is expected to amplify investment in Indonesia and taxpayers' pastime in growing their businesses in Indonesia. There are numerous reason why SMEs are lazy to pay taxes. First, the lack of socialisation of the tax authorities on the duties and ease of paying taxes for Micro, Small and Medium Enterprises. Second is the lack of assistance from the Regional Government to help micro, small and medium enterprises. The third is the pattern of micro, small and medium enterprises transferring from offline to digital platforms. Unlike what was once finished (Wijoyo et al., 2021). It was once found that SME enterprise actors do now not understand the type of tax stimulus because what is regarded as a tax stimulus is a pre-employment assistance, the family hope program.

The socialisation of tax relaxation is needed as an effort to socialise government insurance policies so that taxpayers are better acknowledged and understood, thinking that tax rest is transient because the tax relaxation policy is issued employing the government for taxpayers who are below economic pressure or are affected with the aid of the COVID-19 pandemic. The benefits of socialisation include the skill of disseminating the coverage and the purpose of socialising tax rest so that taxpayers recognise the approaches for filing tax relaxation, the types of tax relaxation, and taxpayers taking a positive role. Wardani and Wati (2018) found empirical proof that taxation socialisation has an impact on individual taxpayer compliance. Kilo et al. (2022)

found that tax justice had no impact on SMEs taxpayer compliance, while tax appreciation had a fantastic effect on SMEs taxpayer compliance and tax socialisation. Sukei and Yunaidah (2020) located that there was once the effectiveness of tax socialisation on taxpayer pleasure and compliance.

Completeness of tax relaxation files is a prerequisite for submitting functions for taxpayers to take advantage of tax relaxation. Minister of Finance Regulation Number 44/PMK.03/2020 regarding incentives for taxpayers affected by using the 2019 Corona Virus Disease Pandemic. The necessities for SMEs that will apply for tax rest or tax incentives have gross profits of not extra than 4.8 billion per year, put up a PP23 certificate, the application submits a document on the realisation of the last PPh borne with the aid of the government via the www.pajak.go.id. (Leong et al., 2020). Evidence is that some SMEs in Malaysia attempt to enhance and get financial assistance from the authorities and that ordinary respondents are comfortable with the help provided by using the authorities at some stage in the Covid-19 period.

Taxpayer compliance is a person's conduct in pleasurable tax obligations and carrying out all his tax rights (Ambarwati et al., 2021). With the tax leisure policy during the COVID-19 pandemic observed that appreciation of guidelines and the benefits obtained from the tax rest policy impacted taxpayer compliance in reporting Article 21 Income Tax Returns. Alm et al. (2020), located tax compliance via the usage of a behavioural approach that attitudes toward behaving, subjective norms and behavioral manage affect taxpayer compliance (Lestary and Yudianto, 2021; Saad and Abdullah, 2014). The taxation socialisation and understanding of taxation positively affect SMEs taxpayers' compliance.

RESEARCH METHODOLOGY

This research is carried out to identify the cause and effect of the relationship between expertise variables of tax relaxation, socialisation and completeness of documents on SMEs taxpayer compliance, a pattern of 172 micro, small and medium enterprises in Malang City, which is engaged in the culinary business, fashion, tutoring institutions, automotive, agribusiness, tour and travel, creative products, tournament organisers, cleaning services, had been requested to fill out a questionnaire, but a complete of 158 data may want to be processed. The micro, small and medium enterprises group consists of 62.1% working all day, 29% at some point of the day and 8.9% working at night. A sequence of questions associated with relevant records and information, this research was conducted by combining experimental and survey strategies using a questionnaire about the expertise of tax relaxation, completeness of submitting documents, coverage socialisation and taxpayer compliance. Questionnaires submitted to respondents consist of 1. Demographics of respondents, inclusive of name, gender, income, age, education, and line of business, have been utilised for tax incentives; two Instruments as a capacity of measuring Information: a) Knowledge of tax relaxation; b) completeness of documents; c) coverage socialisation and 4)

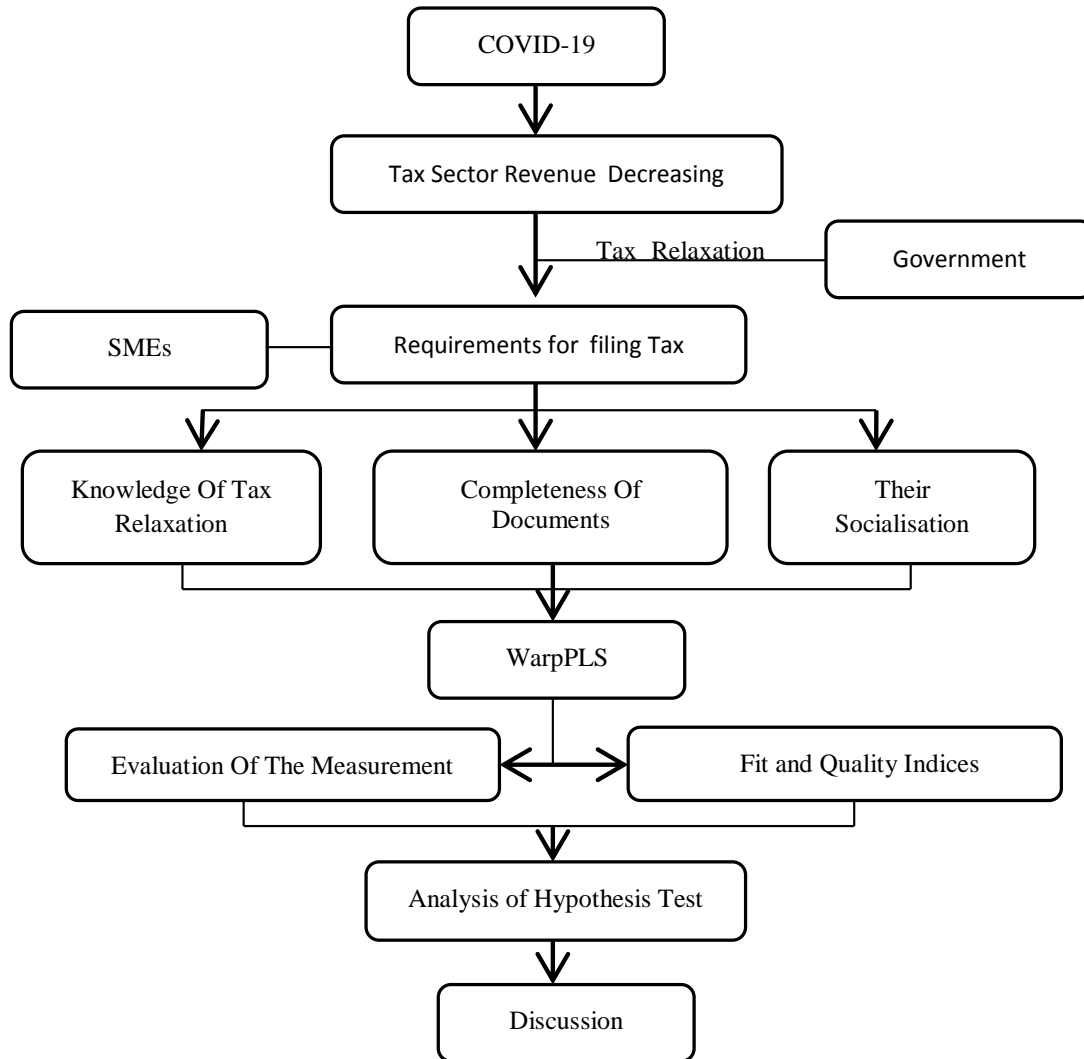

Figure 1. Research framework.
Source: Author

Compliance with: punctual payments, well-timed reports, no arrears, by no means audits and a slow economy. Respondents were requested to fee the instrument using a Likert scale with 1 for strongly disagreeing to 5 for strongly agreeing with answers. Data evaluation and moderation look at used SEM-PLS with WarpPLS model 7.0 approach. WarpPLS analysis does not require the assumption that the data is usually disbursed with a sample resampling of at least 100, so the Central Limit Theorem has been fulfilled, that is, the large the sample, the data will strategies the ordinary distribution of the research framework presented in Figure 1.

RESULTS

This study was carried out in the Lowokwaru sub-district, Malang City, the findings of this study were grouped into: (1) respondent profile on the effects of the identification of SMEs showed that from a whole of 158 SMEs obtained: a) 68.98% male, and 31.02% female; b) age thirty to

forty-five years via 37.24% and 46 to 61 by using 62.76%; c) High college schooling of 41.77%; Bachelor’s degree of 38.36%; d) enterprise sector: meals and beverage using 54.84%, grocery keep by using 28.05%; others using 17.11% and e) income turnover per year between 250,000,000 to 500,000,000 via 68.86%; turnover of 500,000,000 to 1,000,000,000 by using 27.89%; and above 1,000,000,000 via 4.25%. (2) The summary of the check consequences is introduced as follows:

Result evaluation of the measurement model (Outer model)

Convergent validity

Validity of the measurement model was a reflective warning signs based totally on a component loading

Table 1. Loading and cross-loading test results.

| Variable | Indicator | | (r) | P value | Type |

approach, and indicators measuring latent variables that show indications of tax leisure knowledge, document completeness, socialisation and taxpayer compliance have mirrored the latent variable with a correlation coefficient price > 0.4. SMEs taxpayers' ability to know the kinds of tax relaxation on how to practice tax rest and the requirements for acquiring tax relaxation services have reflected the measurement of tax rest knowledge (TRK). Indicators: the completeness of the Annual Tax Return (SPT), SMEs comprehend the deadline for submitting the completeness of the tax relaxation submission record on 30 June 2020, the deadline for submitting the Annual Tax Return on 30 April 2019 for the company and non-public taxpayers who do bookkeeping at the top of the economic yr on 31 December 2019, SPT

attachments Financial statements include stability sheets, income statements and depreciation lists and transcripts of quotations from the elements of the financial statements reflecting the measurement of document completeness (CR).

Indicators: tax regulations, direct information and counselling and seminars have mirrored the dimension of the socialisation of the tax relaxation coverage (SC). Indicators: compliance with registering, compliance with returning tax returns on time, compliance with paying tax arrears together with Tax Collection Letters (STP) before maturity and compliance with paying tax evaluation arrears (SKP) before maturity has reflected the dimension of taxpayer compliance (COMP). Summary of loading take a look at the effects in Table 1.

Based on Table 1, the indicators for every latent variable have reflected the dimension of tax leisure knowledge, coverage socialisation, report completeness and taxpayer compliance, namely the loading thing fee > 0, four.

Composite reliability

Summary of composite reliability takes a look at outcomes introduced in Table 2. Based on Table 2, the know-how variable tax rest (TRK), coverage socialisation (SC), record completeness (CR), and taxpayer compliance (COMP) have a composite reliability price of 0.7. This indicates that all symptoms of each variable have correct reliability to the latent variable.

Table 2. Composite reliability.

| Variable | Composite reliability |
|---------------------------------|-----------------------|
| Knowledge Relactation Tax (TRK) | 0.879 |
| Completed Requerment (CR) | 0.970 |
| Socialisation (SC) | 0.906 |
| Compliance (COMP) | 0.864 |
| Mediation CR * TRK | 1.000 |
| Mediation CR * SC | 1000 |

Fit and quality indices

Based on Table 3, the standards for the goodness of the mannequin show that the mannequin was fashioned by using the completeness of the mediating record of the relationship between the expertise of tax rest and its socialisation on taxpayer compliance is good. P-value < 0.001 from ARS and AARS potential that the mannequin formed is excellent and vast according to ARS and AARS. Meanwhile, based on R-squared, the value of 0.813 was obtained once. The consequences of the WarpPLS analysis in this study confirmed that the magnitude of the variety of data from an understanding of relaxation, coverage socialisation, and completeness of archives that can be explained via the mannequin is 81.3% while the final 18.7% is defined by way of other variables not located in this study.

Figure 2 shows the effects of the moderation evaluation used to discovered the completeness of the documents that enhance the relationship of tax relaxation expertise to taxpayer compliance through 19% and p 0.001 ability that some of the completeness of archives understood through the taxpayer tax leisure information. So in a way is nonetheless restrained to the completeness of

economic report attachments as a complement to the submission of annual tax returns and transcripts of quotations from monetary declaration elements, whilst the completeness of archives can give a boost to the relationship between tax rest coverage socialisation and compliance. Taxpayers at 33% and p 0.001 skill that as far as taxpayers recognise in the cloth for the socialisation of leisure insurance policies for the duration of the Covid-19 pandemic, taxpayers get new records about submitting tax incentives, about strategies for submitting tax relaxation, the required archives in filing tax rest and the types of taxes that acquire tax incentive amenities. In this case, the function of completeness of documents in submitting tax relaxation is very influential in increasing taxpayer compliance through the Covid-19 pandemic because the completeness of archives is the principal prerequisite for submitting tax relaxation. On the other hand, this discovered the obstacle that SMEs taxpayer compliance in applying for tax rest were only limited by using the completeness of financial declaration documents due to the fact that SMEs had to restructure, obtain instalment extend amenities and the government made it less complicated for them to take new loans capital and the depletion of uncooked substances due to

the implementation of restrictions on community activities.

Analysis of hypothesis test

Table 4 shows the analysis of hypothesis test on the direct and indirect effect.

DISCUSSION

The know-how of tax rest (TRK) and coverage socialisation (SC) affects taxpayer compliance (COMP) with p price < 0.001 whilst the oblique effect is that document completeness (CR) as a moderating variable can make stronger the effect of tax relaxation understanding (TRK) on taxpayer compliance (COMP) as well as that record completeness (CR) can reinforce the impact of tax rest policy socialisation (SC) on obligatory compliance tax (COMP) with p-value < 0.001.

Consumer behaviour studies, study every individual, team or organisational motion in choosing, buying, using and evaluating products to satisfy their desires. Taxpayer compliance has interesting and plausible opportunities (Saad and Abdullah, 2014). The learn about taxpayer conduct can be developed along with improving client behaviour studies. Taxpayer compliance research grew

more interesting when the authorities issued a Tax Relaxation coverage aimed at SMEs throughout the COVID-19 pandemic. In theory, the importance of taxpayer compliance in carrying out tax duties by guidelines and laws, however, taxpayer compliance does not only imply being obedient in reporting taxes and paying taxes (Rahayu et al., 2019) but the completeness of archives plays a function in growing obligatory compliance. The inconsistency of this study when in contrast to research (Ambarwati et al., 2021) with the authorities in tax relaxation for the duration of the COVID-19 pandemic and the advantages derived from this policy, taxpayers still comply with annual SPT reporting despite a decline in profits tax revenues that passed off in 2020 due to limit in people’s earnings and purchasing power. However, when it is related to the lookup performed via (Sukesi and Yunaidah, 2020); (Wardani and Wati, 2018); (Saad and Abdullah, 2014), this study helps the lookup performed (Sukesi and Yunaidah, 2020) and (Leong et al., 2020) which conclude that the know-how of tax rest affects SMEs compliance and socialisation of tax rest policy impacts on SMEs compliance.

Conclusion

Based on the results of this study, it can be concluded

that the know-how of tax relaxation and socialisation of tax relaxation policies affect SMEs' taxpayer compliance. The completeness of the tax leisure submission file is a moderating variable between the expertise of tax relaxation and its socialisation on taxpayer compliance, which means that the completeness of the file can extend the relationship between understanding of tax rest and policy socialisation on SMEs taxpayer compliance to reap tax rest facilities. Based on the conclusions of this study, the pointers for SMEs and tax authorities are as follows: First, the tax relaxation policy or tax incentives have a deadline for submissions that have to reply to authorities' insurance policies for the continuity of SME operations, as nicely as the importance of completing enterprise legality and satisfying tax tasks beginning from following and imposing regulations on taxation.

Second, the Tax Service Office wishes to measure the fulfilment of the desires and objectives of the socialisation of coverage starting from resources, communication, bureaucratic structure and disposition, content material of the policy and the implementation environment heavily influences the success of policy socialisation.

Recommendation

The results of this study are addressed to the tax service office as an extension of the directorate general of taxes in disseminating every policy product aimed to the taxpayer community should be able to carry out continuous socialisation and carry out widespread socialisation using the media that is most in demand by the public.

CONFLICT OF INTERESTS

The author have not declared any conflict of interests.

ACKNOWLEDGEMENT

The author would like to thank the perpetrators of micro, small and medium enterprises in Malang City, which are engaged in the culinary business, fashion, tutoring institutions, automotive, agribusiness, Tour AND Travel, Creative Products, tournament organisers, cleaning services, who have been willing to spend time as respondents in this study.
